INTRODUCTION

We, the members of the Spices Enquiry Committee appointed by the Indian Council of Agricultural Research, have the honour to submit herewith our report on the terms of reference forwarded to us.

Early in 1951, the Planning Commission brought to the notice of the Ministry of Food and Agriculture that the attention paid to the development of six important dollar-earning crops of South India, viz. pepper, cardamom, ginger, turmeric, cashewnut and lemon-grass was very inadequate. The Ministry of Food and Agriculture, accordingly, constituted a high level committee to obtain basic information needed for a study of the situation with a view to considering what specific measures are necessary for developing the production and marketing of these six agricultural products.

MEMBERS AND TERMS OF REFERENCE

The personnel and terms of reference of the Spices Enquiry Committee were announced in the letter No. F. 63(4)/51-A dated the 23rd October, 1951 of the Indian Council of Agricultural Research, New Delhi. The following were appointed as members of the committee:—

- r. Shri K. R. Damle, I. C. S., Secretary to the Government of India, Ministry of Food & Agriculture, and former Vice-President of the Indian Council of Agricultural Research, New Delhi—Chairman.
- 2. Shri A. K. Menon, former M. P.—Member
- 3. Shri N. Alexander, former M. P.—Member
- 4. Dr. B. N. Uppal, Agricultural Commissioner with the Government of India, I. C. A. R., New Delhi—Member
- Dr. M. B. Ghatge, Agricultural Marketing Adviser to the Government of India, New Delhi—Member
- Dr. T. G. Shirname, former Agricultural Marketing Adviser to the Government of India and present Director of Agriculture, Bombay State—Member
- 7. Shri C. M. John, Director of Research, Central Coconut Research Station, Kasaragode—Member
- 8. Shri J. V. A. Nehemiah, Secretary, Indian Council of Agricultural Research, New Delhi—Member-Secretary
- 9. Shri M. B. Nayar, B. Sc. (Agri.), M. Sc., Officer on Special Duty

Shri A. K. Yegna Narayan Aiyer, Retired Director of Agriculture, Mysore, who was also appointed as a member, could not accept that office for health reasons but has given his suggestions in writing to the committee.

The terms of reference of the committee were "to examine the whole position regarding the production and marketing of six agricultural commodities, viz. pepper, cardamom, ginger, turmeric, cashewnut and lemon-grass oil and make recommendations as to how the production and marketing of these commodities could be improved". The committee was also asked to see whether centralised direction was necessary and feasible and, if so, in what form to bring about the desired improvements.

QUESTIONNAIRE

A draft questionnaire was drawn up and was approved in a special meeting. It is reproduced in Appendix I. According to the terms of reference, the questionnaire was classified into 10 major heads, viz. production, cultural practices, irrigation, marketing, grading and standardisation, export, transport and storage, finance, cooperative marketing and miscellaneous. The questionnaire was circulated to the State Governments concerned, Directors of Agriculture, growers, traders and other interested individuals. Replies to the questionnaire were invited by the 30th November, 1951, but this date was subsequently extended to 31 December, 1951. In all 2,338 copies of the questionnaire were sent out and 86 replies were received, of which 17 replies were from officials and the remaining 69 from non-officials. The answers to the questionnaire were very varied and in many cases vague. The Officer on Special Duty, hence, prepared a digest of the replies and collected a lot of supplementary information and circulated the same to the members from time to time.

MEETINGS

The committee held several meetings during the period of its working to consider the various replies and suggestions made.

STUDY TOURS

Some of the members of the committee and the chairman undertook study tours in important areas, *vide* page ix, where the agricultural commodities specified are grown with a view

to obtaining a closer knowledge of the problem. These tours were instructive and furnished the committee with a good deal of material for their discussion. During these study tours the committee also considered it important to take evidence of leading cultivators, traders, representatives of cooperative societies and government officials of the various tracts, irrespective of whether they had replied to the questionnaire or not, to get a knowledge of the agricultural conditions and problems of the growers of the particular agricultural commodities, and to get their suggestions for effecting improvements. The evidence of over 250 growers and 30 officials was taken.

ACKNOWLEDGMENT

We desire to place on record our considered appreciation of the cooperation rendered, particularly by the Governments of Madras, Mysore, Travancore-Cochin and Coorg during the various enquiries we conducted in those States. We also wish to record our appreciation of the assistance rendered to the committee by the various State officials and the cooperation they gave in bringing round the cultivators, traders and other interested persons to give evidence before the committee. The committee was particularly impressed by the keen interest taken by officials, non-officials and Ministers of the different States and their eagerness to bring about improvements in the production and marketing of the agricultural commodities specified, importance of which to the agricultural economy of the States concerned has not received proper recognition so far.

We thank all those individuals, associations and bodies and cooperative societies who helped us in our task and particularly the growers who gave frank evidence before the committee and brought to our notice their specific problems and difficulties.

We desire also to place on record our high appreciation of the services rendered by the Officer on Special Duty, Mr. M. B. Nayar, who prepared a digest of the replies received to the questionnaire, collected supplementary information, helped the committee members in drawing up their programme of work, made arrangements for their study tours and prepared preliminary draft reports for their consideration. It would not have been possible for the committee to cover such a wide field without his zeal, devotion and hard work.

GENERAL OBSERVATIONS

We observed a general sense of awareness on the part of the growers, officials and non-officials of the importance of the agricultural commodities, particularly to the coastal region. There is a feeling among them that these agricultural products which have assumed importance in the economy of the country, particularly as dollar-earners, have not received proper recognition and that there has not been any organised efforts for improving the production and marketing of these commodities on the lines of the work done in regard to tea, coffee and rubber. The need for better planning, more agricultural research and coordinated efforts in executing developmental measures were pointedly brought to our notice measures which should substantially increase production and result in financial gains both to the growers as well as to the governments concerned. We feel that the development of these commodities should be considered as an important aspect of agricultural development work in the regions where these agricultural commodities are grown and that urgent measures should be taken in this regard as very little attention had been paid so far to these crops in spite of the fact that the value of exports in 1951-52 from some of these crops was over 23 crores of rupees.

In making its recommendation the committee has been particularly careful to avoid suggestions which cannot be implemented by the government easily. While the committee has made an extensive study of the subject and has given exhaustive factual information to enable the government to formulate developmental policies, its recommendations have been limited to those which could be implemented without undue difficulty during the next 5 to 10 years.

Kalpetta (Wynad)	January 19, 1953	Public enquiry and dvisit to plantations
Calicut	January 20, 1953	Visit to M/S Pierce Leslie and Co's cashewnut processing factory
Cannanore	January 22, 1953	Public enquiry and visit to Madras pepper research stations
Kasargode	January 23, 1953	Public enquiry
Mangalore	January 24, 1953	Public enquiry

CHAPTER I

PEPPER (KALI MIRICH)

GENERAL OUTLOOK

Black pepper, which has become an important article of international commerce, is produced chiefly in India and Indonesia. Borneo, Siam, Sarawak, Indo-China, and Ceylon and more recently Brazil are other important sources of commercial pepper, but the annual supply from these sources is comparatively small.

The world's present pepper crop and the share of different countries have been estimated and are given in Table I.

TABLE I
Estimated pepper crop in different countries of the world

Countries	Pre-war (1938-39) (tons)	Post-war (1951-52) (tons)	Increase (+) o	
			tons	per cent
India	18,500	- 21,500	3,000	+ 16
Indonesia	62,000	10,000	52,000	84
Borneo, etc.	4,000	2,000	-2,000	_50
Indo-China	4,000	2,000	2,000	—sc
Sarawak	4,000	5,000	÷ #,000	·+· 2 5
Others	1,000	विव नवने _{3,000}		+ 300
Total	93,500	43,500	50,000	— 53

The above figures show that the world supplies of pepper have declined considerably during the post-war period. As compared with 93,500 tons produced before world war II, the present supply of this spice is reckoned at only 43,500 tons showing a total fall in world supplies to the extent of 50,000 tons or 53 per cent. These figures also clearly show that this steep fall is solely due to the loss of the Indonesian crop. Except a slight increase noticed in India and Sarawak and a few other countries such as Brazil and Ceylon, there has been a general curtailment of production in all the other major producing countries.

During the war, there was large-scale destruction of the pepper plantations in Indonesia as a result of which the supply from that

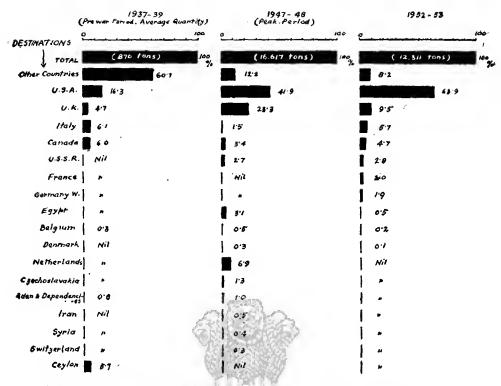

Fig. 3. Percentage export of pepper from India to different countries of the world

बक्सम्बद्धाः ज्ञान

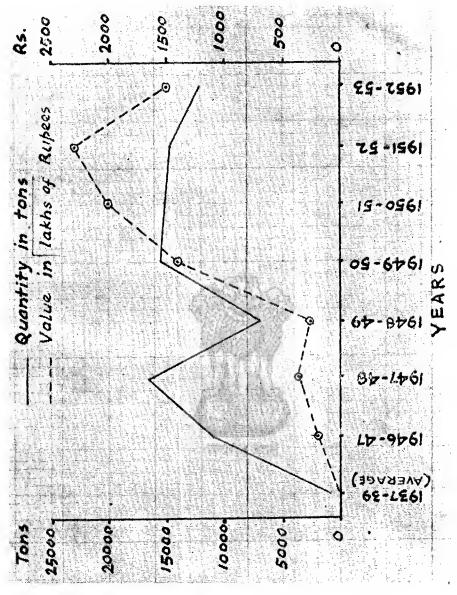

Fig. 4. The trend of export of pepper from India

सन्त्रपंत्र नवने

source declined from 62,000 tons to a meagre 10,000 tons, showing a reduction of 84 per cent. Similarly, the production in Siam, Borneo and Indo-China has also fallen and has resulted in a total reduction of the pepper crop in these regions by nearly 75 per cent from 74,000 tons to 19,000 tons. Although vigorous attempts are being made by these countries to replant their gardens and to rehabilitate their pepper industry, the progress is reported to be slow on account of many practical difficulties and the supply position in these countries is not expected to improve for some more years. It is against this background of continued post-war shortage of world supplies that we should view the problems of the pepper industry in India and frame plans for its development.

Due to the general shortage of supplies, the world trade in pepper has also declined during the post-war period. On an average, the net pre-war annual exports of pepper from principal sources amounted to 60,000 tons (vide appendix IV). As compared to this, the quantity of this spice entering international trade at present is estimated to vary from 22,000 tons to 25,000 tons. Before world war II exports took place mainly from Indonesia and other countries of South-East Asia and India's share in the international trade in this spice was insignificant. Since the commencement of the war, the demand for India's black pepper has steadily grown, particularly in the U.S.A. and Europe and bulk of the world's present requirement of this spice is being met by exports from this country. As against less than 1,000 tons exported before the war, the exports of pepper at present from India to the overseas markets have increased to nearly 15,000 tons.

The present shortage of world supplies has been solely responsible for focussing world's attention on India's pepper crop, but the Indian industry should utilise this opportunity to gain the confidence of its foreign customers and try to retain the present position in the world markets by giving satisfaction to them in respect of both the quality and price of this product.

2. Position of the industry in India

(i) Some facts regarding cultivation

The pepper plant, *Piper nigrum*, L. is indigenous to the forests of Travancore and Malabar and has been cultivated in India from time immemorial. The large-scale cultivation of the crop is largely confined to the sub-montane tracts in and below the western ghats of Penninsular India and covers the State of Travancore-Cochin and Malabar and South Kanara districts of Madras. To a smaller extent, the crop is grown in parts of Mysore, Coorg and Bombay. The crop is met with also in Assam in Sylhet and Khasi Hills but its cultivation in these regions is not at present of any commercial importance. Generally speaking, the pepper belt of India consists of the Malabar coast extending from Konkan (North Kanara) in the north to Travancore-Cochin in the south.

The pepper plant is grown on living trees or other supports known as 'standards'. It is a perennial shrub which lasts in the plantations for 25 to 30 years, although in some of the well-maintained gardens, the life of the vines has been found to be over 60

years. It grows from almost sea level up to an altitude of 3,500 feet above the mean sea level but the coastal sandy regions are not found very suitable for the successful cultivation of this crop. The soils found most suitable for the crop are the clay loams but it is widely grown on red loams and sandy loams overlying the lateritic hill tops of the western ghats. As compared to the soils of the East Indies, which consist of fertile and volcanic rock debris, the soils of the pepper tracts in India are poor and depleted and yield poorer crops. It is an unirrigated crop which is raised solely with the help of the monsoon rains. Being a tropical plant, the crop thrives best in humid and moist climate and in regions where the average annual rainfall is well over 80 inches (vide Appendix III). Places having an average rainfall of less than 50 inches are not considered suitable for the cultivation of pepper. The crop tolerates a minimum temperature of 50°F, and a maximum of 104°F. The propagation of the crop is done vegetatively by means of cuttings.

As already stated, the pepper vine is a woody climber and requires some support for growing. The supports or 'standards' used for the purpose in Indonesia, Borneo and other countries of South-East Asia consist of dead-wood posts, but in India, invariably living trees are preferred. Any of the existing jungle trees are used for the purpose or sometimes seedlings of the local murukku tree (Erythrina indica) are specially planted at a regular distance of about 10 feet and the pepper vines are planted at the base of these 'standards'. The vine grows quickly on this 'standard' and covers it with its dark green foliage and forms into the shape of a bush around the 'standard'. Though the pepper vine grows to a height of 30 feet and more depending upon the growth of the 'standard', each bush is not allowed to grow beyond 20 feet in order to facilitate the picking of the pepper spikes when mature.

The vines begin to flower from the middle of July, and depending upon the varieties planted, the berries become ripe for harvest from January to March. When ripe, the berries assume a beautiful orange or cherry colour. The fruits, which are small berries carried on slender spikes, begin to appear from the third year after planting. The out-turn of the crop is poor at the first harvest and goes on increasing up to the sixth year; from the seventh year onwards full yield can be expected from the plantations.

The preparation of commercial black pepper from the harvested berries is simple. The whole spikes with the berries, are spread on a mat or clean floor and rubbed between the hands or trampled under feet in order to separate the berries. These are then dried in the sun for 5 or 6 days. When fully dry the outer skin becomes black in colour and shrunken in size and assumes the characteristic wrinkled appearance of the black pepper of commerce. The Indian supply consists mostly of this quality of pepper.

In Indonesia and other countries of South-East Asia, white pepper is also prepared for commercial purposes. Both white and black peppers are derived from the berries of the same pepper plant, *Piper nigrum*, L. The only difference is that in preparing white pepper, the outer black skin has been removed from the berries by soaking them in water immediately after harvest and trampling them under feet later in order to remove the outer skin. The supply of white pepper in India is very small and is not of any commercial importance.

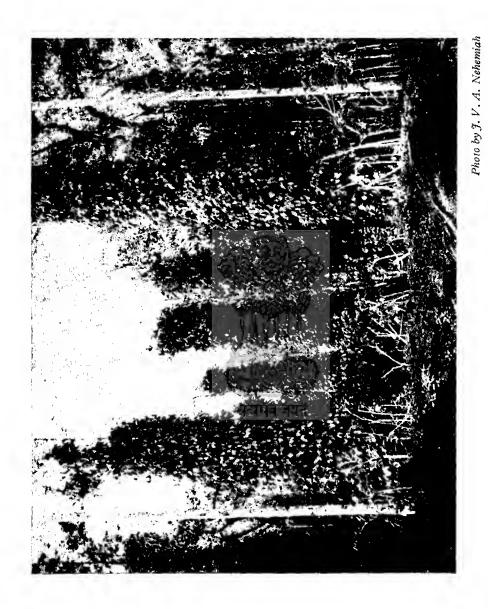

Fig. 5. Pepper vincs growing on jungle trees and the local murukku tree (Erythrina indica) in Wynad, Malabar district

Fig. 6. Pepper vines growing on jungle trees in Wyand, Malabar district

There are roughly three systems of pepper cultivation practised in India. The first system consists of clearance of jungle lands and large-scale cultivation of pepper in the sub-montane tracts and lower altitudes. This system is prevalent in Travancore-Cochin, Malabar and South Kanara. While clearing jungles for pepper cultivation the existing trees are left undisturbed in Travancore-Cochin to be used as 'standards' for growing the pepper vines and separate 'standards' are not, therefore, provided. On the other hand in Malabar and South Kanara, before starting the pepper plantation, the entire hill slopes are cleared of all vegetation and separate 'standards' of the local murukku tree (Erythrina indica) are planted at nearly 10 feet apart. The cuttings of pepper vines at the rate of 5 to 10 cuttings per 'standard' are then planted in small pits on the northern and eastern side and a little away from these 'standards'. The southern aspects are always avoided as the after-noon sun in the summer months may kill the vines outright or cause sun-burns. Nearly half the length of cutting is planted inside the pit and the soil around the planted cutting is pressed hard and heaped up to prevent rain water from getting in and causing water-logging. The free ends of the pepper cuttings above the ground are then pressed close to the 'standard' and tied together with a rope. The tying of the growing vines on the 'standard' is then attended to periodically to keep pace with the growth of the vines. Although 5 to 10 cuttings are planted at the base of each 'standard', more than half of these do not survive and only 2 to 4 vines generally grow around each 'stand-The vines respond very well to manuring. Applications powdered bean-cake, fish guano, dried prawn refuse and burnt topsoil have been attended with good crop yields in the countries of South-East Asia. But in India manure is not generally applied to the pepper gardens particularly in big plantations and except one or two weedings and hoeings given around the base of the pepper bushes, very little after-care or cultivation is bestowed. On an average, there are 300 to 400 'standards' per acre and the yield of commercial black pepper has been found to vary from \(\frac{1}{4} \) lb. to 2 lb. per 'standard'. Accurate costs of pepper cultivation are not available in any of the producing areas. But according to some owners, the cost of establishing and maintaining a pepper plantation of three acres consisting of 1,000 'standards' up to the fifth year works out to Rs. 3,000 at the present rates of wages. The initial costs of clearing the jungle and preparatory cultivation are very heavy and according to the same source nearly half of this expenditure is incurred on these items, during the first year itself when starting the new plantation.

The second system of pepper cultivation consists of growing mixed crops in the house-compounds and outlying areas at the foot hills and coastal regions. Under this system, pepper vines are grown only on existing trees such as jack, mango or even coconut and arecanut grown in the gardens. The number of pepper vines owned by the individual cultivators under this system is small and these are generally well-cared for, and as a result some of these vines have been found to live for more than 60 years, although the normal life of a large-scale pepper plantation is estimated at only 25-30 years. Though only a smaller proportion of the pepper crop is grown under this system it is this group which offers immediate scope for intensive cultivation and development.

The third system of pepper cultivation is as an inter or subsidiary crop along with other plantation crops like coffee, cardamom and orange and is practised to a small extent in parts of Coorg and Mysore. The owners in these cases are big planters and are not directly interested in pepper cultivation. This subsidiary cultivation has become popular only in recent years and planters in these areas are not quite sure whether such inter-cropping would adversely affect the yield of their main crop.

(ii) Differences in crop estimates

Until recently pepper was grouped under spices and condiments and no separate statistics of its area and production were recorded in the agricultural returns. Since 1948-49, the importance of this crop has been fully recognised and the Directorate of Economics and Statistics began to publish regular crop forecasts of the pepper in India.

According to these published crop forecasts, the area under pepper in India during 1951-52 was 1,92,231 acres out of which 1,02,500 acres were distributed to the Madras State in the two districts of Malabar and South Kanara while the State of Travancore-Cochin accounted for 85,768 acres. The other pepper producing areas, viz. Bombay, Coorg and Mysore, together accounted for only 3,963 acres.

Although these official figures indicated a reduction in acreage as compared to those of 1948-49, new pepper vines have been planted everywhere, in many of the house-compounds and outlying areas in Travancore-Cochin, Malabar and South Kanara and that the increase in acreage thereby could be reckoned at 5 to 10 per cent in recent years. On a rough calculation, there are at present 75 million pepper 'standards' in India of which 70 million represent old pepper bushes and the remaining represent new vines planted during the post-war period.

The production of black pepper according to official forecasts published for 1951-52 amounted to 27,916 tons from 1,92,231 acres. Various trade representatives who gave evidence stated that these official figures were grossly over-estimated and that their estimate of the pepper crop in India for the same period was very much less, not exceeding 19,000 tons. In their view such discrepancies were not new and existed for the past several years as indicated in Table II.

TABLE II
Discrepancies in the estimates of pepper production in India

Year	Estimated official production (tons)	Trade estimate (tons)	Difference (tons)
1948–4 9	30,619	22,000	+ 8,619
1949-50	31,165	20,000	+11,165
1950-51	30,570	18,000	+ 12,570
1951-52	27,916	19.000	+8,916

It will be seen that the official estimates of production varied from those of the trade by as much as 12,570 tons in certain years. On examination it was found that this discrepancy was largely due to the exaggerated crop estimates from Travancore-Cochin, which is the most important among the reporting States, included in the official crop forecasts (vide Appendix V). In the pre-war days, when India exported only small quantities of pepper to the world markets, such discrepancies in crop estimates were not of much consequence. At present, however, bulk of the Indian crop is exported and international price quotations are bound to be greatly influenced by the crop estimates emanating from official sources. We, therefore, consider that steps should be taken to reconcile such wide discrepancies and to examine the basis of crop reporting in all the producing areas, particularly in Travancore-Cochin. A more rational basis for the determination of area and normal yield should also be evolved by conducting pilot statistical surveys.

(iii) Total production

In view of the differences in crop estimates pointed out to us, we have estimated the production figures for 1951-52 on the basis of the evidence collected by us. According to these estimates, the total production of black pepper in the different States of India during 1951-52, has been as follows:

Travancore-Cochin	12,00 tons
Madras (Malabar and South Kanara)	9,000 ,,
Bombay (North Kanara)	150 ,,
Coorg Mysore and other States	150 ,, negligible .
यसमान सम्ब	21,300 tons

It will be clear that pepper production in India is concentrated in the two southern States of Travancore-Cochin and Madras which together account for 98 per cent of the pepper crop in 1951-52. Travancore-Cochin is the major producing area and accounts for 56 per cent of the total crop. In this State, the most important sources of supply are the talukas of Thodupuzha, Muvattupuzha, Vaikam, Chenganacherry and Meenachil (Palai). Madras State ranks second in importance and accounts for 42 per cent of the pepper production in India. In Madras, pepper production is confined to the northern talukas of the Malabar district and the Hosdurg taluka of the South Kanara district. In both these States, production is carried on in small holdings and nearly 60 per cent of the cultivated holdings have been estimated to be under one acre in size.

Pepper is produced also in Sirsi, Coorg and parts of the Malnad area of Mysore State but the annual output from these sources is relatively small, and accounts for hardly two per cent of the total Indian crop.

In the absence of reliable crop estimates for the previous years, the trend of pepper production could not be ascertained. But on the basis of pre-war crop of 18,000 tons, the present pepper production in India shows an increase of 3,300 tons or 17.8 per cent. The present

enhanced production is attributed not so much to the extension of pepper cultivation to new areas as to the intensive methods of cultivation and better attention paid by the garden owners. In 1952-53, 85 to 90 per cent of the normal crop amounting to 20,700 tons only is expected showing a decline of nearly 600 tons as compared to the figures of the previous year.

It is clear that the Indian production has not kept pace with the increase in the world demand for the produce during the postwar period. Internal production should therefore be stepped up and greater attention should be paid towards intensifying agricultural practices in the existing gardens than in opening up new plantations. The details of a co-ordinated Ten-Year Plan for intensive development of the pepper crop in India should be worked out by the Central Government and put through expeditiously. In preparing this plan, the object sought to be achieved is that India should be in a position to export almost the entire present annual output to meet the demands of the foreign markets and that the internal requirements of this product should be met out of the increased production. resulting from the proposed Ten-Year Pepper Development Plan. As the present pepper gardens consist of many old and uneconomic pepper bushes, a systematic attempt should first be made to replace these by improved varieties in all the pepper tracts. Arrangement should be made to complete such replacements in the course of the next five years so that at the end of 10 years, all the pepper gardens will consist of only the bearing vines of the improved types. Special nurseries will have to be raised for the purpose and other technical and financial facilities will have also to be provided for carrying out the intensive cultivation and adopting control measures against pests. and diseases.

There are many local varieties (vide appendix VI) and most of the gardens consist of a mixture of many varieties. The yield of the pepper gardens varies widely in the different producing areas depending upon the soil, fertility, cultural practices, nature of varieties grown and the age of the pepper bushes. On account of all these factors the average yield of pepper crop is found to vary from 100 lb. to 300 lb. per acre. The poorest yield is reported from the Malnad areas of Mysore where the average yield of commercial black pepper does not exceed 100 lb. per acre. Almost the same yield is obtained in the Sirsi area of North Kanara where it amounts to 112 lb. In Malabar and South Kanara, the average yield of the pepper gardens is estimated to be 250 to 300 lb. per acre. The maximum average yield noticed in Travancore-Cochin amounts to 350 lb. per acre. The average yield of all these areas works out to slightly more than 2 cwt. per acre, whereas under improved practices the out-turn of all these gardens could be considerably increased.

(iv) Foreign imports

Very little black pepper has been imported into India from foreign countries in recent years. The imports during 1951-52, amounted to hardly 118 tons and consisted mostly of cheaper Indonesian pepper reexported from the Straits Settlements. Other sources of imports are Burma, Java, Kenya Colony, Hong Kong and some of the British possessions. Bulk of the imports however, consisted of re-exports from the Straits Settlements and was received through the West.

Bengal ports. The total supply of black pepper in India consisting of the indigenous production plus imports thus wroks out to 21,418 tons during 1951-52.

(v) Foreign exports

India has always been a net exporter of black pepper to the foreign countries. The quantities and values of black pepper exported from India since 1937-38 are given in Table III.

TABLE III

Quantity and value of pepper exports from India during 1938-39 to 1951-52

Year	Quantity (tons)	Value" (in lakh rupees)
1937-39	870	3.7
1946 -47	11,001	206.5
1947-48	16,617	372-1.
1948-49	7,052	<i>1</i> 67·13
194950	15,631	7450 5
1950-51	15,394	2040·3
1951-52	14,873	2317 · 1
1952-53	न्यापदाय,उग	159610

As compared with nearly 900 tons exported before the war, the present exports of black pepper from India have increased to nearly 15,000 tons. From hardly two per cent before the world with II, India's share of the world pepper trade increased to more than 70 per cent during the post-war period. Owing to the unprecedented increase in pepper exports, there has been a steep rise in pepper prices in India and the value of the exports, therefore, increased considerably during the post-war period. While in 1938-39 the total value of pepper exports from India was only Rs. 3.4 lakhs, it increased to Rs. 206.5 lakhs in 1946-47, and amounted to as much as Rs. 2317.1 lakhs during 1951-52. The fall in exports noticed in 1952-53 was mainly due to speculative buying in the U.S.A.

The exports of black pepper to the foreign markets take place mainly through Cochin. Nearly 10,000 tons were shipped from this port alone during 1951-52. After the development of the port at Cochin, the importance of other west coast ports such as Alleppey, Calicut, and Mangalore has declined.

During the war, considerable quantities of pepper were exported from the Bombay ports. These were mostly re-exports of the produce obtained from Malabar and Travancore-Cochin.

The main market for Indian pepper is the United States of America. Nearly 30 per cent of India's pre-war exports went to this country. Immediately after the war, the total exports from India increased greatly from 873 tons to 11,002 tons. As much as 38-1 per cent of this enhanced shipments also went to the U.S.A. In 1950-51, the total exports increased still further to 15,394 tons and the share of the exports to America amounted to 69-7 per cent. During the pre-war years America used to import nearly 24,000 tons of pepper mostly from Indonesia. At the present time, the American demand is estimated to be of the order of 14,000 tons out of which 56-3 per cent is at present met by the Indian supplies. Though bulk of India's present exports go to the U.S.A., there is further scope for expanding that market and increase the dollar-earnings of this country.

The main destinations and the share of different countries in the pepper exports from India are given in appendix VII.

Although India exported pepper regularly to the U.S.A. and Canada during the post-war period, there has been occasional off-take of this Indian product from other hard currency areas also such as Mexico, Cuba, Columbia, Bolivia, Guatemala, Haiti, Ecuador, Honduras, Panama, and Salvador. The imports into these countries are relatively small and sporadic but the scope for export promotion in these areas should be examined by the Indian Government Trade Representatives concerned.

Among the other markets for Indian pepper, the U.K., Italy, the U.S.S.R., Egypt, Aden and dependencies are the most important. While other producing countries have special organisation in the U.S.A. and other consuming countries for promoting exports of their countries' products, the Indian trade appears to be handicapped greatly by lack of arrangements for propaganda and publicity even in important markets. All sections of the Industry who gave evidence impressed upon us this lacuna in our foreign trade and pointed out that the Indian Government Trade Representatives alone could not do this job. Their hands are too full with other products to devote undivided attention to spices. Unless separate agencies are set up at the destinations as is done by other producing countries and as in the case of other commercial crops, wholetime attention will not be given and our export trade is bound to suffer. Besides foreign publicity and sales promotion, these agencies should closely follow the consumer requirements and competition from other countries and undertake to supply regular information regarding prices, quality, etc. to the home market. In order to facilitate exports and sales promotion, a documentary film should also be prepared of the various processes of the industry and exhibited not only in the foreign markets but also in the non-producing areas of Upper India.

Generally, the exports to foreign countries are only of one quality known as the 'garbled' pepper. 'Garbled' pepper is clean and dry and is generally free from dust, dirt, etc. The proportion of light and hollow berries is also the minimum in these samples. The exports to the U.S.A. and other foreign markets are only of the 'garbled' quality. There are not many complaints as regards the quality of pepper exported from India nor has there been any increase in the claims preferred by the foreign buyers on the basis of quality. The quality of the pepper exports from India is, therefore, considered satisfactory.

We would, however, take this opportunity to mention some of the malpractices of the trade which have come to our notice. Old lots of pepper and rejections after garbling are of inferior quality and have a dull appearance. In order to give the berries the shining black appearance of natural pepper this stuff is smeared with a coating of white oil. Besides improving the appearance smearing with this heavy mineral oil also increases the weight of the sample which is also taken advantage of by the sellers. Oil-washing is, however, objectionable from the point of view of public health and certain countries like the U.S.A. have statutorily prohibited the import of such products. We are also told that small fruits of many jungle shrubs and trees particularly of Lantana, and Vitex altessiona which resemble the pepper berries are specially gathered and dried and adulterated with the pepper berries. These practices damage the prospects of establishing firm trade relationship with the foreign countries and should be discouraged. More recently, in the middle of 1952 the Indian shippers suffered heavy losses on account of the detention of many consignments in the U.S.A. on account of insect infestation. These had to be cleaned and reconditioned at the shippers' cost before admission into the U.S.A. Steps should be taken to avoid such losses in future by conducting our foreign trade on the basis of standard qualities. What is required at the moment is to standardise the quality of our pepper exports and win the confidence of our customers by supplying them with specified standards.

Many foreign buyers demand certificates of origin, quality and weight as regards consignments of pepper shipped from India. Several trade associations have therefore made arrangements on their own to conduct "chamber survey" and issue the required certificates in regard to these quality factors of pepper and other spices. In order to avoid confusion in these standards it would be better if definite grades and grade specifications are framed on an all-India basis under Agricultural Produce (Grading Marketing) Act and these specifications are adopted by the trade and included in their trade contract terms.

For export purposes, pepper is generally packed in double gunny bags, with a capacity varying from 1½ cwt. to 1½ cwt. While the outer bag is new, the inside one is often old. Although the present methods of packing appear to meet with general approval of the trade, we would recommend that new gunny bags should be used even for inside packing in order to prevent any possible contamination. Along with framing of standard qualities for pepper, the packing should also be standardised for export purposes.

Most of the export trade from India is at present carried on according to the contract terms prescribed by the American Spice Trade Association of New York (vide Appendix VIII) or the General Produce Broker's Association of London (vide Appendix IX). In both these contracts, there is no provision for mutual allowances for quality or for arbitration facilities in India in the case of disputes between the parties. The arbitration facilities are provided either in New York or London and the Indian shippers are generally not in a position to avail of the same. Steps should, therefore, be taken to prepare Indian Standard Contract terms for pepper as well as for all other spices and to persuade the importance to agree to provide arbitration

facilities in India and to be governed by our proposed standards of quality and packing which will be specified in the Indian Trade Contract Terms.

(vi) Dollar-earnings from export

The total value of the pepper exports from India and the amount of dollar-earnings during the four years ending 1952-53 may be seen from Table IV.

Table IV

Dollar-earnings from the exports of black pepper
(in lakh rupees)

Year	Total value of exports	Amount earned in dollars	Percentage
1949-50	14,50.5	814.7	56.1
1950-51	20 40 · 3	1509.0	73.9
1951-52	23,17.1	1301 8	56.1
1952-53	15,95.7	I 127 ° 0	70.6
Average	18,50.9	1188 1	64.2

The value of the total exports has varied from Rs. 14.5 crores to Rs. 23.17 crores during the last four years, the average value of annual exports being Rs. 18.5 crores. Out of this income from exports, Rs. 11.88 crores representing 64.2 per cent were earned in hard currency.

Since November 1949, the Government of India has levied an export duty on pepper at the rate of 30 per cent ad valorem with a maximum of Rs. 150 per cwt. Although this duty was levied in order to minimise the effects of speculative activities and to serve as an anti-inflationary measure, the Central Government have already received a revenue of Rs. 12:04 crores as duty alone during the four years ending 1952-53. Roughly Rs. 7:34 crores of this duty were received from the exports from Travancore-Cochin and the remaining Rs. 5:6 crores from the Malabar crop including that of South Kanara and Coorg.

None of the witnesses who appeared before us complained about the high rate of duty or of its incidence but they have unanimously represented that the Central Government should take early steps to develop this industry particularly in view of the large revenue received from this article alone. We are convinced that very little organised effort has been made either by the respective State Governments or by the Central Government to develop this industry on modern lines. The State Governments concerned are too involved in their 'grow more food' programmes and their representatives have informed us that they cannot afford to divert any funds for the development of the pepper industry. The Central Government should therefore provide for all assistance both financial and technical for developing this industry which affects the prosperity of millions of peasants in these producing areas. Considering the present world

shortage in this spice, the potentialities of expanding our foreign trade in this product and thereby improving the revenues of the State are also great. Details of a Ten-Year Plan for the development of pepper should be worked out and put through expeditiously, with the three-fold object of stepping up production, reducing costs of production and expansion of internal and foreign markets.

(vii) Internal demand

Since world war II and especially after the partition of India, the quantities of black pepper distributed in internal trade have gone down considerably. As compared to a pre-war demand of 9,000 to 10,000 tons, the quantity of black pepper distributed in various parts of India at the present time (1951-52) is estimated to be nearly 5,000 tons. The estimated quantities can be seen in Table V.

Table V

Estimated utilisation of black pepper in different States during 1951-52

States	Pre-war utilisation (tons)	Post-war utilisation (tons)	
Madras	1640	306	
Mysore	200	100	
Bombay	320	6∞	
Madhya Pradesh	150	100	
Delhi and Punjab	335	800	
Uttar Pradesh	800	600	
Bengal	3430	1000	
Assam	600	300	
Orissa	150	100	
Others	1380	600	
Total	9000	5000	

The quantities distributed in internal trade have been reduced by nearly half during the post-war period. The quantity of pepper distributed in the internal markets has also become very poor. It consists of a large proportion of hollow and light berries and a considerable amount of foreign matter. In spite of high prices, good quality pepper is unobtainable in the Indian markets. The various trade associations in India, should take note of this situation and try to ensure reasonable satisfaction as regards the quality of the produce distributed in the internal markets. The main sources of supply in all the internal markets continue to be the west coast districts of Malabar and Travancore-Cochin.

For internal trade the produce is moved mostly by means of coastal steamers and bulk of the produce is transferred from Alleppy and Cochin. Formerly, half the quantity entering internal trade used to

be moved to Bombay and the other half to Calcutta which are the two important distributing markets for northern India. In recent years, however, Calcutta has become the main distributing centre for the northern States while the quantities moved to Bombay are mainly for re-exports to the foreign markets.

Besides coastal steamers, part of the movement of pepper to the north Indian markets is done by rail. The rail exports take place from Cochin and Tellicherry and are despatched to Madras, Bangalore, Bombay, Delhi, Kanpur and Calcutta. After receipt at Calcutta the subsequent distribution is also done on rail. Accurate statistics of either the coastal or the rail traffic or of carry-over stocks are not, however, available.

Considering the general shortage of supplies, we should aim at releasing as much as possible of our present crop for meeting the demands of the world market and try to step up local production to the extent of meeting our internal requirements.

(viii) Prices

Pepper prices have shown phenomenal rise during the post-war period. In no other agricultural commodity has this rise in prices been so marked as in the case of black pepper. It has been observed that the main staple food crops like rice have registered an increase of only 3½ times since the war started which is in parity with the general rise in the post-war price level. Copra and coconut oil have increased by nearly 7½ times. Even other spices of these areas like ginger, cardamom and turmeric have shown a rise of only 5 to 7 times over the pre-war level. In the case of pepper alone the post-war rise in prices has been of the order of 36 times in certain years. This rising trend of post-war prices may be clearly noticed both in internal and world-markets as shown in Table VI.

TABLE VI

Trend of black pepper prices at Cochin and New York

Year	Cochin		New York	
	Price per candy (6 cwt.) Rs.	Price index	Price per 1b. in Cents.	Price index
1939	108	100.0	3.9	. 100.0
1946	384	355-5	39.1	1002*5
1947	570	527.7	43.8	1123.0
1948	690	638 · 8	62.2	1584 · 8
1949	2286	2116.6	100.0	2564 · 1
1950	3174	2938 · 8	189.0	4846 •1
1951	4158	3850.0	160.0	4102.5
1952	3942	3650-0	140.0	3589.7

In India, Cochin is the most representative market for black pepper while New York, being the largest importing centre, forms the index of world market prices. The phenomenal rise in both these markets may be clearly seen from the table.

The average annual price of pepper at Cochin amounted to hardly Rs. 108 per candy of 6 cwt. in 1939. It increased to Rs. 384 towards the end of the war and by 1948 reached the level of Rs. 690. Till 1949, the rise has been gradual but it suddenly shot up to Rs. 2,286 in 1949 and increased still further in the subsequent years. The average annual price in 1951-52 stood at Rs. 3,942. The outbreak of the Korean war and the increased off-take from the U.S.A. have largely contributed to this boom in Indian pepper prices. During this time considerable speculative activities have also been reported. As compared to a price index of 100·0 in 1939, it rose to 355·5 in 1946 and 3650:0 in 1952 representing an increase of nearly 36 times over the pre-war level. In New York also similar rising trend of pepper prices during the post-war period has been noticed. From hardly 3·9 cents per lb. in 1939, the prices of pepper rose to 140 cents in 1952 representing an increase of nearly 35 times (vide Appendices X. XI and XII).

In both India and the world, the maximum price levels were reached during 1951 and since then there has been a slight recession in the prices but considering the present world shortage of pepper and the slow progress of rehabilitation in other countries it is not likely that this recession in prices will continue very much further. Anyway this is a commodity in which much speculative trading takes place and should therefore be constantly watched by the Forward Markets Commission for purposes of regulation.

The garbled quality is a much cleaner product and contains light and hollow berries below 3-5 per cent and other foreign matter below two per cent. The foreign exports are mostly of this quality and fetch a higher premium of Rs. 200 per candy (6 cwt.).

The daily export prices of pepper are published in almost all the important local papers in the producing areas. But the producers are generally unable to derive the full benefit of this price and work back the parity level on account of the differences in the units of price quotation. Correct dissemination of world prices in a manner intelligible to the producers is, therefore, necessary.

In spite of this phenomenal rise in pepper prices, the producers do not feel enthusiastic to extend pepper cultivation. The main reason is that they do not feel confident that the existing high prices will continue and do not, therefore, want to take any risk. Moreover, pepper vines take four to five years to give any satisfactory return and majority of the small producers are not prepared for this period of waiting. They need quick returns and, therefore, prefer the cultivation of root crops or cereals which besides yielding seasonal returns also serve as food in these scarcity areas.

There has, therefore, been no appreciable extension of pepper cultivation in India. This indicates that more than the phenomenal rise in prices, what is required is a more stable price level for stepper internal production.

(ix) Assembling and distribution

The important assembling and distributing markets for pepper are in Travancore-Cochin, Malabar, and South Kanara. While production of pepper is concentrated in the foot-hills of the ghats, these markets are on the coastal towns located within 50 to 100 miles of the producing areas. The names of important markets and the quantity of pepper handled at these during 1951-52 are shown in the Table VII.

TABLE VII

.Estimated arrivals of black pepper in some important markets during 1951-52

State	Interior market	Assembling & dis- tributing market	Quantity handled (tons)
Travancore-Cochin	Palai	Alleppey	2000
	Kottayam	,,	1000
	Thodupuzha	Cochin	4000
	Muvattupuzha		1000
Madras	Ponknnam	,,	1000
(i) Malabar	Wynad	Calicut	2000
	1/11/2	Tellicherry	2700
	Iritty, etc.	Beliapatam	2500
(ii) South Kanara	Kanhangad	Mangalore	1500

The total arrivals in Travancore-Cochin markets during 1951-52 have been estimated at 9,000 tons out of which nearly two-third of the crop is assembled at Cochin and the remaining one-third at Alleppy. Before the war, Alleppy handled larger quantities of pepper, but after the development of the Cochin port, Cochin has become the main important assembling market for pepper. Since foreign exports also take place from these centres, these markets serve as both assembling and distributing markets.

The total arrivals in other producing areas consist of 8,000 tons, distributed in Calicut, Tellicherry, Beliapatam and Mangalore. In Coorg and Mysore, there are no assembling centres for the crop. Almost the entire surplus from Coorg is moved to Tellicherry and assembled there. Bombay, Sirsi and Siddapur are important centres, but the quantity assembled at these centres is very small. Besides these arrivals, the retention in villages and the carry-over stocks with the merchants and by producers are said to be of the order of 2,000 to 3,000 tons.

As already stated, the interior markets are situated in the foothills of the ghats and consist of hilly tracts which do not have proper roads or even foot-paths connecting the producing area. Improvement of road communications in these areas would, therefore, greatly facilitate the marketing of pepper in these areas. In the interior markets situated within a radius of 3 to 10 miles from the producing villages, pepper is sold in small lots of 5 to 10 lb. It is generally carried to the market in head-loads by the producers themselves and sold to the village merchants. The village merchant buys the whole lots on payment of cash. Although no market charges are levied or collected from the producers, deductions for charity, loss of weight and allowances for quality are invariably made by the village merchants. The units of weight adopted in the village transactions are also not uniform. On account of these practices, the producers in the village markets have not derived the full benefit of the post-war rise in pepper prices.

When the village merchant assembles a sizable quantity of pepper such as a candy weighing 6 cwt., he arranges to transport the same to the main assembling markets situated in the sea-coast towns. There, the produce is delivered to the commission agents. These commission agents keep the produce in their godowns without charging any godown rent. But they charge a commission ranging from 11 to 2 per cent of the value of the produce. There are also customary deductions on account of what is locally known as poti palam which literally means dust in the sample. Whether the sample contains dust or not such deductions are made which invariably amount to 30 to 40 lb. per candy of produce, representing nearly 5 to 6 per cent. of the weight of the sample. In view of this practice the incentive for selling cleaner samples is lost. The commission agent makes payment in part and settles the account after final disposal of the produce. Besides commission, other marketing charges payable by the seller are for brokerage, weighment and charity. All these charges are deducted before making final payment to the village merchants. Before the war, these commission agents stocked considerable quantities of pepper in their godowns and used to sell it to the shippers as and when there was demand. But during the postwar period, many of the big planters have begun to hold back considerable quantities of their annual crop and release it only when prices are more favourable. Most of these assembling markets are also terminal markets for pepper. The shippers and exporters also, operate in the same market and they invariably get their supplies from these agents. The commission agents arrange to transfer the produce to the shippers' godowns according to orders. The shippers arrange for pepper garbling of the produce in their own godowns and after garbling, the produce is packed in double gunnies and exported to the foreign markets.

While these assembling and terminal markets were found to be more organised than the primary markets, there are still many charges and deductions which are not sustainable on the grounds of the service performed by these agencies and should, therefore, be regulated. The unit of weight adopted for sale in both these areas is one candy of 6 cwt. but the candy has been found to vary from 600 lb. to 700 lb. at different places. It is advisable to prescribe one uniform weight for the candy at least in the main West Coast markets of Travancore-Cochin, Malabar and South Kanara.

In countries like the U.S.A., the markets are either owned by farmers and businessmen or they combine to form a non-profit private corporation to finance and operate the marketing activities by means of which the farmers and dealers save time, reduce distribution costs and derive all the advantages of central direction such as 128 I.C. of A.R.

pooling, grading, publicity, etc. They get expert advice from the various government departments and thus are able to realise the benefits of institutional or group marketing as opposed to the marketing by individuals. In India, where nearly 60 per cent of the production is in small and scattered holdings, it would be advantageous for our producers to adopt a similar method for the marketing of their produce and combine themselves into village co-operatives. It was stated in certain quarters that such co-operative institutions would not work satisfactorily in the west coast. The working of the Travan-core Co-operative Wholesale Society at Alleppy and the Malabar District Co-operative Rroduce Sales Society Ltd. do not, however, support this view. Besides pepper, these societies handle other products like ginger, coffee, copra, etc. and have shown steady progress in their volume of business as well as in membership. The main difficulties experienced by these societies in the expansion of their business were lack of finance and adequate storage facilities. If proper godowns are made available in the villages and the Apex banks be persuaded to give larger financial accommodation to these village societies, the development of co-operative marketing in the case of pepper and all other cash crops would in our opinion make much headway in the main pepper tracts. When a large number of such village societies are established these could be united into district unions and brought under a State or regional federation. With experience and State assistance, such co-operatives could gradually develop their business and handle the foreign export trade also. In order to increase the returns of the small producers and to improve their bargaining power particularly in times of price recession, such. co-operative agencies can play an important role.

(x) Uses of pepper

Pepper is an indispensable item for sauces, soups and curries and has been used in this manner in India from very ancient times, particularly by those whose living standards are higher. It is an important ingredient in many Ayurvedic preparations and is used in this form to a small extent. By far the largest quantities imported into the United States of America are utilised in the meat packing and food canning industries. The grinders in the U.S.A. also prepare powder for table use.

3. RESEARCH, TECHNOLOGY AND DEVELOPMENT

(i) Need for scientific research

In spite of the importance of pepper to India, particularly in the West Coast districts, very little research work has been done on this crop. In Travancore-Cochin, which is the most important producing area for pepper, one pepper farm at Konni was started, but the Government closed down the station in 1948 after conducting some piece-meal items of research work. In the Malabar district, the Madras Government has been carrying on some research on the pepper crop at the Taliparamba Agricultural Research Station for some time. But this farm which was originally meant for dealing with pepper has now been converted into a multi-purpose research station and is not exclusively devoted to the research on pepper. Recently, however, the State Government has opened one Pepper Research Station at Panniyur which is close to the Taliparamba farm

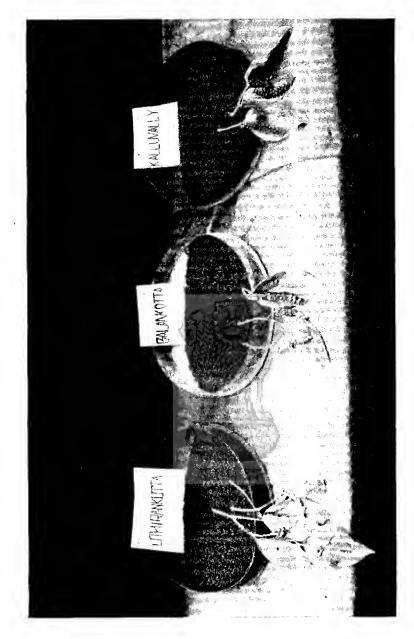

Fig. 7. Three varieties of Malabar pepper. Note the compact nature of spikes in Kalluvalley as compared to the sparsely set grains in others.

सन्त्रपंत्र नवने

and is situated only 5 to 6 miles away from it. These farms are not, however, found to be representative of the larger part of pepper-growing areas of the Malabar district. Although the Indian Council of Agricultural Research is already financing a pepper research scheme in Madras, a revised scheme for co-ordinated research should also be prepared in the light of the above observations. In both Travancore-Cochin and Malabar, the regional problems awaiting solution are different and almost every witness whom we examined stressed the need for conducting scientific research in these regions for improving the yield and quality of the pepper crop.

(ii) Improving planting material

The cultivated varieties of pepper-vine are numerous and each tract has its own selection of local varieties. In Malabar and South Kanara, the most popular varieties are locally known as Kalluvalli, Balam cotta and Cheriya kodi. These varieties account for nearly 50, 30, and 20 per cent respectively of the cropped area. In Travancore-Cochin, the most popular variety is known as Kaniya Kadan which occupies 50-60 per cent of the pepper area in the State. Other varieties are Kotta nadan, Karivilanchi, Perimkodi, Kumbha Kodi and Chumala. In Mysore and North Kanara, the varieties are locally known as Malligasari, Marata, and Doddiga. Appendix VI shows the names of the local varieties and their chief characteristics. Most of these local varieties have been evolved by the cultivators themselves and so far no attempt has been made to breed improved types.

Many witnesses who gave evidence before us complained that one of the major difficulties experienced by the cultivators, particularly the owners of small gardens, was the lack of an adequate supply of reliable planting material. Even if sufficient number of cuttings were obtained at high prices, the quality and performance of the vine was not assured. In a perennial crop like pepper which lasts in the plantations up to 30 years and more, such risks cannot be undertaken. It is therefore necessary to take urgent steps to raise a large number of special pepper nurseries in different producing areas and arrange for an adequate supply of reliable planting material. In every pepper garden more than one variety of pepper vine are met with and these consist of good and regular yielders as well as poor and irregular yielders. Our object should be to replace all the poor and uneconomic vines by means of good and regularly yielding varieties in the course of five years.

As the vines raised from rooted cuttings begin to yield earlier and establish better than the ordinary cuttings, the supply should consist mostly of rooted cuttings. These cuttings for the nurseries may be selected from high yielding and improved types of vine during the months of October-November when these are in the full bearing stage so that the nursery-men can be sure of their performance. This system of raising rooted cuttings is being practised in Malaya and has also been tried with success at the Taliparamba Research Station in Malabar. Although there are no special difficulties of raising such rooted cuttings, yet the number of nurseries will have to be large in order to meet the demands of different producing areas.

When an adequate supply of planting material is available, particularly in the West Coast and arrangements made for replacing pepper planting week should be organised all over the pepper tract,

all the old and uneconomic vines in each garden and for the planting of such rooted cuttings. This should be carried out on a systematic basis at the rate of one-fifth of every garden in a year so that the whole replacement work may be carried out in the course of five years. Sufficient inducement should be given to the producers in this connection.

In selecting cuttings for planting purposes, particular emphasis should be placed on one or two economic characters of the plant. The pepper plant produces both bisexual and unisexual flowers. In order to increase the yield, varieties having a large number of bisexual flowers should be preferred for cultivation purposes. Similarly, the proportion of dry commercial pepper obtained from the green berries is also not a constant factor in most of the varieties. The dry weight obtained varies from 33 to 43 per cent in the case of Travancore varieties and 38 to 42 per cent in the case of Malabar types (vide appendix VI). Thus by selecting suitable types the outturn of our pepper plantations could be increased by 5 to 10 per cent.

(iii) Selection of 'standards'

The pepper plant, being a climbing vine is grown on other living trees or supports known as 'standards'. In Indonesia, Sarawak and other producing countries, dead-wood posts are fixed at intervals of 7 to 10 feet and the pepper vine is planted at the base of these standards. In India, however, live trees are generally preferred. While any of the existing jungle tree is used as 'standard' in Travancore-Cochin, the 'standard' consists largely of the local murukku tree (Erythrina indica) and other garden trees in Malabar. Being a tropical plant, the pepper vine requires a humid and moist climate, and the purpose of these living 'standards' seems to be to provide these conditions besides serving as supports for the climbing vines. The effect of various kinds of 'standards' on the successful growth of vines has not yet been studied. If there is no particular significance in having live 'standards', we should encourage the use of deadwood posts of suitable dimensions in the plantations as is done in other countries.

(iv) Soil fertility

Cultivators do not as a rule apply any manure to the pepper gardens, especially when grown in big plantations. In most of the areas, therefore, the soils were depleted and the crop was reported to give very poor yields. A rapid soil survey is necessary in order to determine the level of soil fertility in these areas.

In other producing countries where the gardens are regularly manured with powdered bean-cake, fish guano and dried prawn refuse, the pepper vines are reported to respond well to manuring. The results of the manurial experiments conducted in India at the Konni Farm and at the Taliparamba Agricultural Research Station also have shown that by proper manuring, the yield of our pepper gardens could be increased considerably. Suitable experiments should, however, be conducted in representative tracts to decide their manurial requirements. The results should be utilised for stepping up production.

(v) Control of pests and diseases

Pests and diseases affecting the pepper vines are not many and the economic loss on this account is not serious. However, in some years, the attack of 'Pollu' disease results in the hollowing of the berries and assumes importance, while root-diseases predominate in some other years. Though suitable remedial measures and cure are not available for these, breeding for disease resistance appears to have great potentialities. Among the Malabar varieties, Kalluvalli and Karim cotta show greater resistance to these diseases while Karivilanchi, Valiya Kaniya Kadan and Karuvalli are the more resistant types in Travancore-Cochin. Apart from finding out suitable remedies for these diseases and pests, breeding work for combining the disease resistance of these varieties with other economic characters should also be attempted from among the wealth of plant material available in different localities.

(vi) Improving methods of storage

Pepper is generally immune to the attack of insects. But it has been found that the presence of moisture induces mould formation and as a result of such mouldiness, insect infestation has also been found to occur, in the stored products. The types of insects which have been identified are (1) the book-lice or psocids, (2) cereal mites (3) grain beetles and (4) cigarette beetles. Among these, incidence of book-lice was found to be the maximum. In order to control insect infestation and check mould formation, the moisture content has to be reduced. It is reported that a moisture content of 10 per cent is the marginal limit and any excess moisture beyond this limit will encourage mould formation and insect infestation. The optimum moisture content and other factors should be investigated. Pepper also re-absorbs moisture from the humid atmosphere during storage and transit and this factor should also be taken into consideration while suggesting optimum limits of moisture in commercial samples.

(vii) Technology

The essential oil contained in pepper has some commercial uses. The technological possibilities of extracting this oil should be investigated. However, pepper which is unfit for other purposes should only be utilised for this purpose. The commercial possibilities of manufacturing white pepper should also be explored.

(viii) Maintenance of statistics

The unsatisfactory nature of the statistical information available in the country has already been pointed out. Even in regard to the primary statistics concerning the acreage and production of pepper, wide differences have been noticed between the official and trade estimates. Nor is the position better in regard to stocks and carry-over or internal utilisation. Such statistics are vital to develop the industry on rational lines and should, therefore, be maintained.

SUMMARY OF CONCLUSIONS AND RECOMMENDATIONS

(i) General outlook

Owing to the general shortage of supplies in other producing countries, the present demand for Indian black pepper is likely to continue for some years. As supplies in Indonesia and other countries of South-East Asia improve the price of this spice cannot be maintained for long at the present high level.

The Indian pepper industry should, therefore, utilise the present opportunity and take early steps to reduce the costs of production and distribution so as to enable it to offer more competitive prices in the foreign markets.

(ii) Need for agricultural research

Very little research work has been carried out with a view to improving the quality and yield of the pepper crop in India. Some work has been done mostly in the Madras State with the financial assistance from the Indian Council of Agricultural Research while most of the other producing States have not bestowed adequate attention for the scientific development of this industry. There is urgent need for research for reducing the cultivation expenses and production costs by adopting scientific methods of farming. It is, therefore, recommended that two regional research stations should be started in the two important producing areas of Travancore-Cochin and Malabar and two regional sub-stations at Sirsi in North Kanara and some suitable hill areas of Assam. We understand that the soil and climatic conditions in Assam are largely similar to those of the Malabar coast and that this State offers great scope for extending the cultivation of pepper. Investigations should, therefore, be carried out for popularising pepper cultivation in various parts of Assam.

In order to minimise the expenditure on staff and equipment, it is suggested that these regional research stations and sub-stations for pepper should be utilised for conducting research on other spices and allied crops as well, as far as possible.

(iii) Increasing internal production

For reducing the gap between the present world demand and supply, it is necessary to step up internal production of black pepper. In spite of the stimulus provided by the post-war boom in prices, the acreage under pepper cultivation has not shown any appreciable increase. In order to increase internal production of this spice, we recommend that steps should be taken to encourage (i) intensive methods of cultivation in all the existing pepper gardens, (ii) replacement of old and uneconomic vines in all the existing plantations and (iii) cultivation of pepper in new areas wherever there are possibilities of extending the crop.

(iv) Better basis for crop estimation

Although all-India forecasts of the pepper crop are regularly published, wide differences have been noticed between the official crop estimates and those given by the trade, particularly in regard to the annual outturn of the crop. As such conflicting estimates react unfavourably on the export prices, there is urgent need for reconciling the differences by adopting a more reliable basis for the preparation of official crop estimates. Pilot sample surveys should therefore be u) dertaken to determine the normal yield of the pepper crop in the

different producing areas. Such surveys should also examine the possibility of enumerating the total number of old and new vines in different plantations so as to determine more accurately their yielding capacities.

(v) Special agency for export promotion

The main markets for Indian black pepper are the United States of America and the United Kingdom. While other pepper producing countries have set up special organisations in these foreign markets for promoting their countries' exports, the Indian export trade is built up on the traditional pattern and is carried on in an isolated manner. Consumer research or modern methods of publicity and sales promotion are absent. The hands of the Government of India Trade Representatives abroad are so full that they cannot be expected to devote whole time attention to this commodity alone. It is recommended that the Central Government should set up a special Export-Promotion Agency in New York and another in London with the sole object of expanding India's trade in pepper and other spices by co-operating with similar agencies already functioning at present. The Export-Promotion Agency which has its head-quarters in New York should be entrusted with the work in the U.S.A., Canada and other American markets while its counterpart in London should be asked to take over the publicity and sales promotion work in the U.K. and other European markets.

(vi) Documentary films

Exhibition of documentary films will be an effective aid to greater publicity and sales promotion. The Government of India should prepare documentary films showing the various stages of the pepper industry and of other spices and arrange for their exhibition in all important markets, both present and potential.

(vii) Exploring new markets

Although bulk of the pepper exports from India are to the U.S.A., other hard currency areas such as Mexico, Cuba, Colombia, Bolivia, Guatemala, Haiti, Eucadar, Honduras, Panama and Salvadar have also occasionally taken small consignments of this spice from India during the post-war period. The Government of India Trade Representatives in foreign countries should survey the potentialities of developing these new markets.

(viii) Uniformity in grade standards

Considerable inconvenience and financial loss were recently caused to the Indian shippers due to the detention of some consignments of black pepper in America on the ground that these shipments were insect-infested. Complaints regarding other factors of quality are also sometimes heard. In order to maintain the reputation of Indian black pepper and to give satisfaction to the foreign consumers, it is necessary to frame suitable grades and grade specifications for this commodity under the Agricultural Produce (Grading and Marking) Act, and encourage the shippers to conduct export trade on the basis of these grades and grade specifications These standards of quality should then be included in the trade con tract terms also.

It should be remembered that good quality Indian black pepper is superior to pepper produced by any other country and ensuring the quality of the pepper exported would, therefore, be a sure way of retaining the present favourable position in the world markets.

(ix) Standardising trade contract terms

The present contracts for foreign exports of pepper and other spices are made largely according to the terms prescribed by the American Spice Trade Association of New York or the General Produce Brokers' Association of London. None of these associations provides for mutual allowances of quality or for arbitration facilities in India in the case of disputes. The Indian industry should frame standard contract terms of their own providing for these facilities and utilise the present opportunity in order to persuade the foreign buyers to accept the same.

(x) Uniform weights in West Coast markets

The unit of weight which is adopted for sale of pepper in the West Coast markets is one candy. But the candy is found to vary from 600 to 700 lb. in different markets. Even the pound was not found to be uniform. The Governments of Madras and Travancore-Cochin should agree to take early steps to adopt uniform weights in all the West Coast markets.

(xi) Regulation of markets

The returns of the small producers are reduced by various deductions and customary charges prevailing in the West Coast markets. The deductions on account of driage and quality are often found to work hard on the producers. Improper deductions and market practices should be eliminated by bringing all important assembling centres in the West Coast within the scope of the Regulated Markets Act as soon as possible.

(xii) Co-operative marketing नियमित्र नियम

The role of co-operative agencies in the marketing of pepper was found to be insignificant. In a crop like pepper where nearly 60 per cent of the cultivated holdings are small, the benefits of co-operative marketing are obvious. There is urgent need, for organising Producers' Co-operative Societies for the sale of pepper in all the primary markets. These societies should be gradually combined into District Unions and brought under a State or Regional Federation. The Central and State Governments should encourage the formation of such co-operatives and give all facilities to these federations for undertaking the export trade. Such facilities may also include loans or subsidies for construction of warehouses, etc. and liberalisation of rules governing the issue of co-operative loans.

Wherever there is no scope for organising co-operative societies, the possibilities of establishing licensed warehouses should be considered.

(xiii) Improving road communications

Most of the pepper producing areas are concentrated in the hilly tracts at the foot-hills of the western ghats. Opening up of these areas by means of proper road communications would make these areas more accessible and facilitate the marketing of the produce.

(xiv) Market-news service

Although the post-war boom in pepper prices has made the producers alert, most of them are still ignorant of the market conditions and do not, therefore, derive the full benefits of the prevailing high prices. This is further complicated by the speculative activities of the trade. In order to determine his selling price, the sellers in the primary and secondary market should possess up-to-date information regarding arrivals, stocks, despatches and prevailing prices at various centres. Arrangement should be made for supplying such information regularly to the sellers in the primary and assembling markets by organising a 'market-news' service in the important producing States, including daily broadcasts of these particulars from the regional stations of the All India Radio.

(xv) Central plan for development

We are convinced about the scope and urgent need for the development of the pepper industry in India. In spite of the unprecedented rise in post-war pepper prices, the producers have not made any effort to develop the industry on improved lines. Nor has the State Governments bestowed adequate attention in this regard. Being preoccupied with food production, the State Governments concerned have clearly indicated that they are not in a position to pay proper attention or to divert funds for the development of pepper and other spice crops. The Central Government should, therefore, step in and organise the development of this valuable Indian industry on scientific lines. For this purpose, we recommend that the Government of India should create a Pepper Development Fund and earmark from the export duty a sum of not less than one crore of rupees, for organising and subsidising all the development measures such as supply of standards, raising of special nurseries, supply of rooted cuttings, replacement of uneconomic vines, extension of cultivation, control of pests and diseases, provision of better storage facilities, framing of grade standards, promotion of orderly marketing and dissemination of agricultural information regarding production, marketing, etc.

As a first step, the Central Government should consult the State governments concerned and prepare an integrated Ten-Year Plan for the development of the Indian pepper industry. This plan should also be executed expeditiously.

The governments at the Centre and of the producing areas, as well as the country at large have been greatly benefited by the post-war boom in pepper prices. The duty collected on the exports of pepper by the Government of India during the last four years has amounted to Rs. 12.94 crores of which Rs. 7.34 crores were contributed by Travancore-Cochin and Rs. 5.60 crores by Malabar including South Kanara and Coorg. The pre-war value of annual exports from India amounted to hardly Rs. 4 lakhs which at the present time has increased to Rs. 23.17 crores, more than half of which was earned in dollars. The importance of this industry cannot be maintained unless the Central Government steps in and develops the industry on the lines indicated above.

(xvi) Organisation and control

We have carefully considered the type of agency which should be entrusted with the task of organising and controlling the developmental measures envisaged under the proposed Ten-Year

Pepper Plan. We recommend that a small central advisory committee for development of spices should be constituted by the Government of India. This central committee should be assisted by three regional advisory committees, one for Travancore-Cochin, second for Malabar and South Kanara and the third for Mysore including Coorg and North Kanara. The regional committees should consist of not more than ten persons nominated by the State governments representing government officials, producers, traders and other interests concerned, besides the Chairman who should be the Agricultural or Development Secretary of the regional governments concerned. The regional committees which will not ordinarily meet oftener than once in six months should review the progress of the Ten-Year Pepper Plan in their respective regions and offer their advice on all schemes put up to the government. While the central committee will be responsible for planning and coordination as well as allocation of funds for various developmental measures, the responsibility for the successful working of the Ten-Year Plan and for proper utilisation of the funds provided therein will rest with the three regional advisory committees.

We have recommended the setting up of separate regional committees in the three important pepper-growing areas and have suggested decentralisation of the functions with the sole object of enabling the respective regions to make more effective use of all the local resources and to enlist public co-operation in the development of this important sector of our national economy.

बर्यपंत्र नग्रने

CHAPTER II

CARDAMOM (ELAICHI)

1. GENERAL OUTLOOK

Actual figures of cardamom production in different countries of the world are not available. But judging from the quantities exported from different sources, the principal cardamom producing countries are India, Ceylon, and Indo-China. The crop is also cultivated to some extent in Central America, particularly in Guatemala. The relative importance of these countries may be seen from Table I.

TABLE I

Annual exports of cardamom from different countries of the world
(Quantity in tons)

	Pre-war			Post-war				
Sources	1937	1938	1939	Average	1947	1948	1949	Average
India	650	650	850	716	750	850	1150	917
Indo-China	500	500	500	100	100	*100	100	100
Cèylon	150	200	150	167	100	100	100	100
Total	1300	1350	1500	1316	950	1050	1350	1117

^{*} estimated average

The average world trade in cardamom has thus varied from 1316 tons to 1117 tons and may be reckoned at nearly 1200 tons. It will be seen that both during the pre-war and post-war periods India has been the largest supplier of this spice in the world markets. The average pre-war exports from India amounted to 716 tons which increased during the post-war period to 917 tons representing 82 per cent of the international trade. The shares of Indo-China and Ceylon in the world trade during these periods are relatively small and have not exceeded 100 tons each. The exports from Guatemala consisted mostly of seeds.

Besides being the largest exporter, India forms the only source of true cardamoms in the world markets. The true cardamoms are obtained from the plant *Elettaria* cardamomum which is widely grown in India. These are valued for their higher oil content and aromatic properties and are considered superior to the bigger sized cardamoms obtained from various species of *Amomum* grown in Sikkim, Nepal, Siam, Java, and a few other tropical countries.

Cardamom has an agreeable aromatic odour and is largely used for flavouring and medicinal purposes. In the eastern nations, this article is used for chewing with betel leaves and as a masticatory while in northern Europe, particularly Sweden, Norway, Germany, and the U.S.S.R., the cardamom seeds are powdered and widely utilised for the flavouring of cakes and pastries and for other culinary purposes. It is also used for flavouring of liquors. In medicine, cardamom is employed in the preparation of tinctures and for the extraction of oil. The oil content is by far larger in the seeds than in the husk but the oil obtained from both the husk and the seeds has identical properties and is largely used in flavouring beverages.

The average world demand for all these purposes, is however, limited and is reckoned at 1200 tons. As bulk of this requirement is already being met by supplies from India, the scope for further expansion of India's foreign trade in this product is limited. Instead of trying to expand the foreign trade, steps should be taken to retain the position already gained in the world markets.

2. Position of the industry in India

(i) Some facts regarding cultivation

In India, cardamom grows wild in many portions of the western ghats. It is also cultivated in this region at altitudes varying from 2500 to 5000 ft. The plant prefers a warm and humid atmosphere and a temperature ranging between 50° to 95° F. and thrives best in the shade provided by the lofty forest trees. The crop requires a plentiful supply of humus and a fairly distributed annual rainfall of over 60 inches. On account of these limitations, the cultivation of this crop is concentrated in the moist ever-green forest lands of South India.

The cardamom plant is a tail, herbaceous perennial with branching underground root-stocks from which arise a number of aerial leafy shoots. As these shoots die, new ones are formed in their places. At the base of these aerial shoots one or more branches of flowers arise. The flowers which are borne in panicles open in succession from the base to the top and develop into fruits. The fruit is a trilocular capsule and generally contains 15 to 20 hard brownish black seeds having a thin mucilaginous coating. The shape of the fruits varies according to the variety of cardamom, but is generally plaegreen to yellow in colour when ripe and the fruit-wall or pericarp is firm and smooth.

Depending on the size of the fruits, there are broadly two varieties of cardamoms recognised in India. They are (1) Elettaria cardamomum var. Major Thw comprising of the wild indigenous type and (2) Elettaria cardamomum var. Minor Watt comprising of all the cultivated races included under the names of Mysore and Malabar cardamoms. The wild cardamom is a most primitive variety from which the cultivated forms are derived but all these varieties and races are interfertile and therefore produce many hybrids showing considerable variation in the size of the plant, the nature of the leaf surface and flowering panicles and also in the size of the fruit capsules

The most important cardamom-growing region in India is Travan-core-Cochin. In this State, the crop is grown in the high ranges and is largely distributed in the regions known as the Cardamom Hills. This is grown largely as a single crop on a plantation basis, the size of the plantation often ranging from 50 to 200 acres. Bulk of the

Fig. 9. Elettaria cardamomum var. Minor with trailing panicles (Courtesy C.S.I.R.)

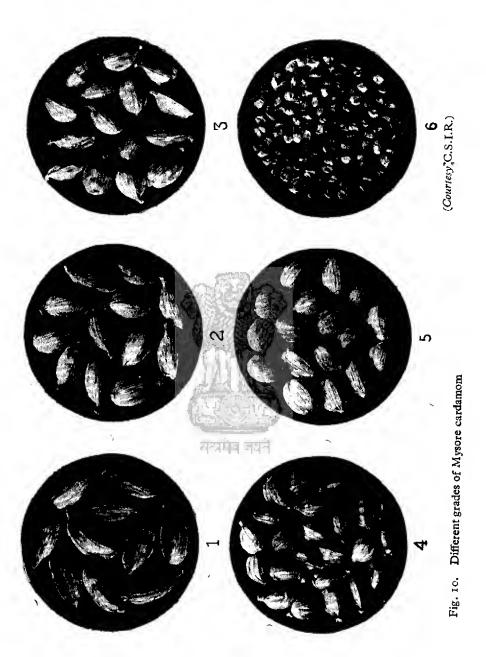

Fig. 11. Capsules of different cardamom varieties.

cardamom of commerce is produced in this region. The next important cardamom-growing area is in Mysore State, particularly in the Munzerabad taluka of the Hasan district. The cultivation in this State is also similar to that of the Cardamom Hills. In Coorg, where the crop is cultivated to a smaller extent, the cultivation is largely confined to the slopes of ever-green forests and is practised as shifting cultivation. After a lapse of 10 or 15 years, the cropped area is allowed to revert to jungle and new plots are selected for raising fresh cardamom crop. Certain portions of Malabar, Nilgiris and Madura districts of the Madras State and North Kanara district in the Bombay State also grow cardamom, but the production from these sources is comparatively small and is often collected as minor forest produce. It appears that in all these places, the cost of clearing the jungle is heavy and the planters also experience scarcity of labour. Even if suitable lands are available, the scope for extension of cultivation is, therefore, said to be limited.

Generally, cultural operations commence in February-March. During this month, a suitable piece of virgin forest land is chosen and cleared of all under-growth-leaving the big trees undisturbed to provide shade. Small pits are dug in the cleared area at a distance of 10 feet and with the onset of the south-west monsoon rains, two year old seedlings or rhizomes from the old cardamom crop with their aerial shoots are planted at the rate of two per pit. In August-September, one or two weedings are given and stagnant water is all drained off. In the second year also sufficient attention is paid to weeding and drainage in the plantation and these operations are continued thereafter only occasionally or according to the labour facilities available. The crop begins to yield from the third year onwards and annually thereafter. Harvesting commences in August-September and lasts upto January or even April. As the cardamom plants do not ripen uniformly, the harvesting of the crop is spread over a long period. The fruits are gathered at intervals of 30 to 40 days and the harvesting is completed in five or six instalments. The first yield is poor and amounts to hardly 20 lb. of dry capsules per acre. By the fourth year, the yield increases up to 30-40 lb. and by the fifth year a normal crop of 60-70 lb. is obtained from the plantation. The average yield was much higher and used to vary from 100-150 lb. per acre in a disease-free plantation. Both Malabar and Mysore varieties of cardamom give about the same yield. The The present reduced yield of the crop is attributed largely to the lack of seasonal rains and incidence of pests and diseases. Among the diseases the mosaic, also called the 'marble disease' or Katte disease, is the most important. It is transmitted by an insect vector, and is characterised by the mottling, curling of leaves and degeneration of the clumps. By systematic roguing of affected plants and planting of disease-free seedlings raised in special nurseries, this disease has almost been eliminated from the growing areas in North Kanara. These methods should be employed in other areas also for the eradication of the disease.

Among the insect pests, thrips cause the most serious damage. Besides reducing the yield of the plants, they damage the wall of the ovary and greatly reduce the market value of the produce. Regular dusting with 'Gammaxene' has been found to be an effective remedy against these pests and is widely adopted in big plantations on a

systematic basis. The Agricultural Department of the respective States should, therefore, popularise these methods of disease and pest control particularly among the small producers. As very little can be done by way of human effort to obtain seasonal precipitations, great emphasis should be placed on this item of extension and development work by the respective Agricultural Departments.

After harvesting, the produce is dried in the sun or in specially built drying houses by means of artificial heat. The devices used for artificial drying vary from sheltered mud platforms heated by a slow fire from beneath to a large drying house or kiln heated by flue pipes. The fruits kept for drying are spread out thinly and are frequently stirred to ensure even drying. The time taken for preparing the sundried cardamom is 3 to 5 days while the produce prepared in the drying houses or kilns by artificial heat takes only 48 hours. The cardamom so dried also retains its green colour and obtains fancy prices in the markets. The sun-dried produce, on the other hand, retains the mucilaginous coating on the seeds and therefore possesses a characteristic sweetish aroma. The dried capsules are then rubbed by hand and winnowed to remove other plant material and foreign matter. The out-turn of dried capsules by these methods varies from 20 to 28 per cent of the green harvested produce.

Sometimes fumigation chambers or sulphur boxes are specially constructed and the cardamom fruits are bleached by exposure to sulphur fumes. The final product is known as the white cardamom or the bleached cardamom of commerce. It is a distinct trade quality. Bleaching is done largely in Haveri, in the Bombay State, which obtains bulk of raw supplies from the Mysore State. Bleaching improves the colour of the outer skin, and preserves better during storage.

(ii) Crop estimates

Reliable statistics of the cardamom crop are not available in India but from the information obtained from official sources and the trade, the area and production of cardamom in the country during 1951-52 have been estimated as in Table II.

TABLE II

Estimated area and production of cardamom (Elettaria cardamomum)
in India during 1951-52

Principal producing		Production		
States	Area in acres	Quantity in tons	Percentage	
Travancore-Cochin	55,738	800	55.8	
Mysore	27,301	350	24 · 4	
Coorg	11,908	200	13.9	
Madras	15,808	75	5.3	
Bombay	619	8	0.6	
Total	111,374	1,433	100.0	

Fig. 12. A three-year old healthy plant of cardamom

सन्त्रमेव नग्ने

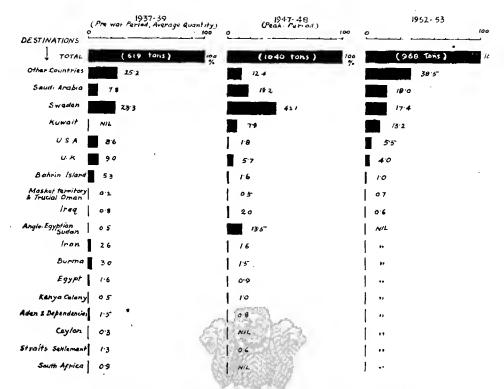

Fig. 13-Percentage export of cardamom from India to different countries of the world-

During 1951-52, the total cardamom crop in India amounted to 1433 tons or approximately 1500 tons. Travancore-Cochin is the principal cardamom-producing area in India and this State accounts for 800 tons representing 55.8 per cent of the total crop of 1951-52. Mysore accounted for 350 tons or 24.4 per cent while the production in Coorg amounted to 200 tons or 13.9 per cent. These are the three major cardamom-producing States and among these three States, over 94 per cent of the Indian crop is distributed. Production in other parts of Madras and Bombay State was comparatively small.

The total cardamom crop of 1951-52 is considered to be below normal. The prospects of the 1952-53 crop are better on account of timely receipt of rains and a normal crop of about 1800 tons was expected.

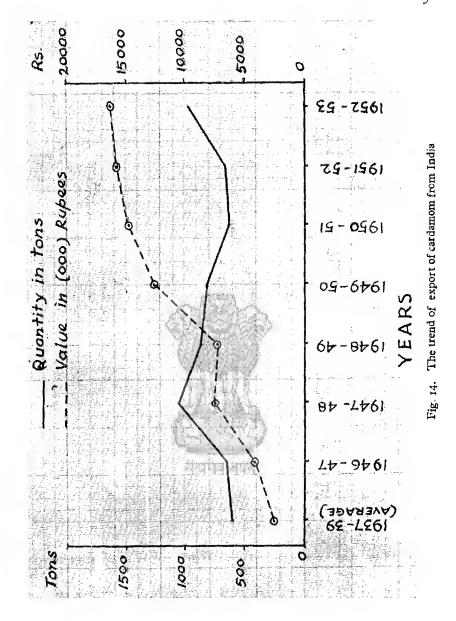

Due to the inaccessibility of most of the producing regions there are many practical difficulties of estimating the acreage under the cardamom crop (vide appendix XIV). The mode of cultivation which varies from pure plantations to shifting cultivation also renders the estimation of acreage difficult. Similarly, the absence of reliable figures of normal yields of the crop has also been a handicap in estimating the total out-turn of the crop. Considering the importance of cardamom particularly in the agricultural economy of the West Coast States, early steps should be taken to evolve a suitable method for estimating the area and yield of this crop and publish regular forecasts of this crop on an all-India basis. Pilot sample surveys should be undertaken in this connection to determine the normal yield of the crop in the different producing areas.

(iii) Exports

There are no imports of true cardamom into India. As already stated, India is the largest exporter of this commodity and forms the main source of supply of cardamom in the world markets. The average pre-war exports from India amounted to 661 tons annually and were valued at Rs. 31.5 lakhs. The quantity and value of the exports have increased since then and during 1952-53, 968 tons of cardamom valued at Rs. 163.7 lakhs were exported from India (vide appendix XV).

The main markets for Indian cardamoms is Sweden and nearly one-fourth of the Indian cardamoms is exported to this country. Sweden imports cardamom both from India and from Ceylon. While the Indian cardamom is used largely for flavouring cakes and pastries the imports from Ceylon are exclusively used in the flavouring of liquors. The next important market for Indian cardamom is Saudi Arabia. It is only since the beginning of world war II, that this country has become our customer. Both Sweden and Saudi Arabia are important markets and nearly 40 per cent of the Indian exports are accounted for by these two countries.

The exports of cardamom from India to the U.S.A. and Canada have, however, been small and the recent trend of shipments also shows a decline. The reduced offtake of the U.S.A. is attributed to competition from Guatemala which supplies cardamom in the form of seeds. The Indian Government Trade Representatives and the proposed Export Promotion Agencies should keep in touch with the market conditions in these countries and see that the exports from India are fully maintained.

सन्त्रपंत्र नवने

The foreign exports can be grouped under three main qualities, namely, (1) green cardamoms (2) white of bleached cardamoms and (3) seeds, the estimated share of each being as follows.

Green cardamoms White or bleached		••	80 pe	r cent
cardar			10	do.
Seeds			10	do.
Total ex	ports		100	do.

The green cardamoms are prepared by drying the harvested fruits in the sun or by means of artificial heat while the white cardamom consists of the bleached capsules. Bleaching is done by exposing the capsules to sulphur fumes. Both in the green and the white cardamoms, there are different grades recognised by the trade. For instance, extra bold, and motta green are some of the trade classifications in the green cardamoms while white cardamoms are designated as No. 1, 2, and 3 with varying proportions of A, B and C qualities. Nearly 80 per cent of the exports take place as green cardamoms. The exports of white or bleached cardamoms and as seeds are comparatively small.

The number of grades and their specifications has been found to vary considerably in different places. In order to have comparable price quotations, it is necessary to frame standard grades and grade specifications for the different qualities of Indian cardamom and encourage trading on the basis of standard qualities.

Cardamom obtained from different regions is found to have specific characteristics as detailed in Table III. These can be utilised in framing suitable grade standards.

TABLE III

Characteristics of Elettaria cardamomum

Variety	Length of fruit (c m.)	Weight of seeds%	Weight of husk%	Volatile matter in crushed seeds%	Ash %	Yield of oil from dry seeds %
Malabar	18.7	0.9	21 ∙1	19.0	3.90	8.4
Mysore	2.10	72.3	27.7	18.3	5.05	7:3
Wild (Malabar)	1.91	7 3 ·3	26.7	20.0	4.30	6.4

For export to the countries of the Middle East, cardamom is packed in new double gunny bags. The superior twill gunnies are always used for this purpose. Shipments of cardamom capsules to Europe and America are packed in cases having a standard size of 19 in. \times 19 in. \times 21 in. or 19 in. \times 19 in. \times 24 in. while those of cardamom seed is packed in cases 16 in. \times 16 in. \times 20 in. the capacity of each case being approximately 112 lb. or 1 cwt.

(iv) Internal trade

Though India exports large quantities of cardamom to the foreign markets, the internal trade is also equally important in this spice.

128 L.C. of A.R.

It is estimated that only two per cent of the annual crop is utilised in the main producing areas of South India and the remaining quantity is almost utilised in the markets of upper and northern India. The marketable surplus from Travancore-Cochin is despatched to Calcutta, Kanpur, Delhi, Amritsar, and Bombay and is sold through commission agents in these distributing markets. Bulk of the Mysore produce moves to Haveri in Bombay where it is bleached and graded before further despatch. Part of it also moves via Coorg to Mangalore where along with the Coorg produce it is bleached or exported as such.

In spite of the importance of internal markets, very little information is available in the producing areas as regards the demand from various centres in northern India. This lack of market intelligence coupled with the better crop during 1952-53 have created almost a slump in the South Indian markets. The marketing departments in these States should, therefore, take early steps to contact the authorities concerned in Calcutta, Kanpur, Delhi, Amritsar and Bombay and examine the possibility of despatching larger quantities to these areas. In order to encourage such a movement we recommend that specially reduced station-to-station rates should be charged for the rail transport of cardamom from the main producing areas in Travancore-Cochin, Mysore and Coorg to the distributing centres in Calcutta, Kanpur, Delhi, Amritsar and Bombay.

Besides the true cardamons of South India the internal trade is reported to consist of considerable quantities of a cheaper and inferior variety of imported produce which is of Sikkim origin. This produce is imported through land frontier routes first into the assembling markets of West Bengal such as Kalimpong, Sonada and Darjeeling. From here, the produce is moved by air to Calcutta and then by rail to Delhi for further distribution in Rajasthan and other consuming centres in Upper India. As these cardamoms have a depressing effecting on the level of prices of true cardamoms of Indian origin the question of regulating their distribution has to be carefully considered. These imported cardamoms are bigger in size and probably belong to the *Ananum* species.

(v) Prices

Due to large accumulation of stocks, the prices of cardamom remained depressed in all internal markets during world war II. With the cessation of hostilities, there was improvement in the foreign trade as well as in the prices of this commodity. The prices have steadily increased in all the markets.

For example, the price of green cardamom amounted to Rs. 104 per maund at Mangalore during 1945-46 which steadily rose to a maximum of Rs. 937 during 1950-51. The prices declined slightly to Rs. 932 in 1951-52 but the recession started during this period continued and the prices of this product amounted to Rs. 603 during 1952-53. A similar trend was noticed in other important markets also. The decline in the present price level is attributed to the larger crop during 1952-53 (vide appendix XVI).

Although there has been a decline recently, the current prices are still nearly five times the 1945-46 prices and are considered too high by the average consumers in India. Unless more favourable

prices are quoted by cutting down production costs to the minimum, the consumption of this spice is not likely to go up.

It has been noticed that the consumers in various markets have distinct preferences for different qualities of green and bleached cardamoms and each superior quality gets a premium of Rs. 1/2/per pound. All such processing and grading is, however, done by the merchants and middlemen. The costs involved could be reduced and the produce sold at more competitive rates if the producers themselves undertake to pool their produce and do the grading before selling the produce.

(vi) Assembling and distribution

After harvesting, cardamom is dried and the produce is taken to the assembling markets without further processing. The main assembling markets for the produce of Travancore-Cochin are situated in the Madras State bordering on the eastern side of the Cardamom Hills, the principal centres being Cumbum, Bodinaya-kanur, Thevaram and Pattiveeranpatti. In the Mysore State, Saklaspur is the most important centre for the assembling of the cardamom crop. Small quantities of the crop are also handled at Mudigere and Chickmagalur. In Coorg bulk of the crop is assembled at Mercara but a small portion of it also moves directly to the exporters and merchants at Mangalore market.

The list of important assembling markets for cardamom and the approximate quantities handled at each centre are given in Table IV

Assembling markets and quantities handled by them

Producing region	Name of the assembling market	Quantity handled annually in tons
Madras	Cumbum	200
	Bod inaykanur	150
	Thevaram	80
	Pattiveeranpatti	80
	Kombai	70
	Pannaipuram	70
	Uttamapalayam	50
	Kudalur	50
Marsana	Rajapalayam	30
Mysore	Saklaspur	275
	Mudigere	50
	Chickmagalur	15
Coorg	Mercara	200

Total

1,320

The produce grown in big plantations is generally brought to these assembling centres by the planters themselves while the owners of small plantations sell their produce to the itinerary merchants who transport the same to these centres. The method of sale adopted in all these assembling markets is the auction system and the producers generally get a competitive price. The buyers are either local merchants or the agents of shippers. The shippers themselves also participate in the auction at some places. While Bodinaykanur and other assembling centres in the Madras State appeared to be better organised, the condition of even the assembling markets in Mysore and Coorg was not found to be satisfactory. Neither the sellers nor the local merchants in these centres had adequate information regarding the supply and demand position or of the prices of the produce in other markets and were not therefore able to derive the full benefits of the auction system of sale. This situation should be improved by organising an efficient market-news service particularly in these two regions.

A small proportion of the cardamom crop is handled in these assembling markets by the members of co-operative societies. The societies working at Saklaspur and Mercara have also shown good progress (vide appendix XVII). The main handicaps experienced by these societies are in respect of finance and facilities for storage of the produce. With adequate financial assistance from Apex Banks and construction of larger godowns, these societies could handle larger volume of business. The Central and State governments should offer special facilities for encouraging sales by such cooperative institutions.

The buyers at these assembling markets clean the produce and sort it out into different trade qualities. They also sometimes do the bleaching and prepare white cardamoms. Shipments take place arter settling the rates by cable and on receipt of the firm order. Some of the exporters in the Madras State who have branches in London and New York appeared to carry on negotiations with their foreign customers through these local branches. The main centres for distributing cardamom in India are Bombay, Calcutta, Kanpur, Delhi and Amritsar. Sales are arranged through commission agents appointed in these markets.

The charges incurred in the assembling of the produce have been found to vary from 8 to 10 per cent of the market price and an equal amount has to be spent further on railway freight and merchandising charges. Standard weights are not also used in all these markets. The Saklaspur maund consist of 28¾ lb. as against the standard maund of 822-2/7 lb. Similarly, the *thulams* of Madras were found to vary from 21 lb. to 25 lb. in various centres. There is considerable scope for improvement in these markets by organising regulated markets for this commodity.

3. Research, technology and development

(i) Opening new research stations

Although the need for scientific aid to cardamom industry was recognised as early as 1940, investigations for the improvement of this industry have not been undertaken in any of the major producing

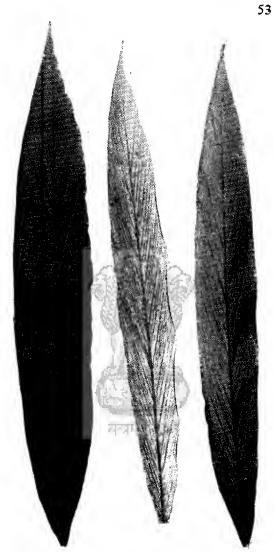

Fig. 15. Healthy (extreme left) and diseased leaves of cardamom.

सन्त्रपंत्र नवने

Fig 17. Rhizomes with roots

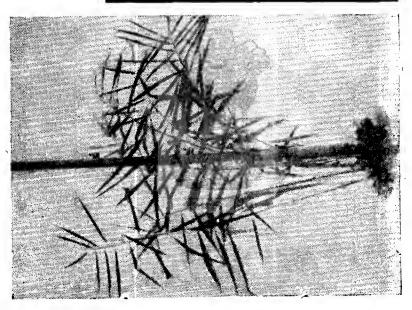

Fig. 16. A ginger plant

सन्त्रपंत्र नवने

regions. Excepting the researches carried out at the two experimental stations of the Madras Government at Singampatti and Valparai, no systematic effort has been made for the improvement of this crop either in the main producing areas of Travancore-Cochin or in Mysore and Coorg which are also important cardamom-growing regions in the country. The need for opening two additional research stations for this crop is obvious. One research station at Saklaspur could investigate the local problems of both Mysore and Coorg. The other stations could be located in Cardamom Hills for studying the problems of Travancore-Cochin. These research stations should conduct particularly cultural and varietal trials for improving the yield and quality of the local cardamom. As cardamom cultivation entails clearance of forests, the effects of such deforestation should also be carefully determined at these research stations.

The cardamom research stations at Madras have found out that regular spraying with 'Gammaxene' is an effective remedy for the control of thrips and other insect pests while the experiments conducted at Sirsi in North Kanara district of the Bombay State have shown that complete eradication of the 'mosaic' disease is possible by roguing the diseased plants and planting disease-free seedlings. These and other results obtained should be given wider publicity and suitable arrangements should also be made for their extension work by the Agricultural Department of the respective States.

(ii) Supply of improved planting material

The cultivated varieties of cardamom are broadly classified as the Malabar and Mysore types. The Mysore type of cardamom known as the Munzerabad variety has smooth leaves, erect panicles and larger fruits having a more or less circular cross-section. This is the bigger and more vigorous type. The Malabar cardamoms are smaller in size. It has prostrate panicles and spherical fruits which are yellow when fully ripe. Nearly two-thirds of the present area in the Cardamom Hills is under this type and the remaining one-third is grown under the Mysore type. One advantage claimed for the Malabar variety is that these plants have prostrate panicles and their fruits are, therefore, beyond the feeding zones of thrips which cause great loss of the crop in these areas. In the case of the Mysore type, the fruits and branches are above the ground and are, therefore, easily accessible to the attack of these insects. The Mysore variety requires also seasonal rains in November-December failing which the yield of the crop is greatly reduced whereas the Malabar type is more resistant. For these reasons, the planters of Travancore-Cochin seem to prefer the Malabar type. Considerable difficulty is experienced by the planters for obtaining supplies of disease-free and reliable seedings and rhizomes. The first item of development should be to organise adequate supply of reliable rhizomes of the Malabar and Mysore types of cardamoms in Travancore-Cochin, Mysore and Coorg.

(iii) Manuring

The planter knows fully the value of manuring but generally it is not a practical proposition in the big cardamom plantations. Well-rotten cattle manure is applied but being in short supply, the plantations are divided into three or four blocks and manure is applied in

rotations once in three or four years. In addition, sheep and fish-manure and leaves of phyllanthus embilica are also applied. Results of manure-mixtures such as three parts of castor cake plus one part of steamed bonemeal plus one part of pottassium chlorate have also given encouraging results in certain areas. These investigations should be carried out in other regions also for confirmation before extending them to the cultivators' fields.

(iv) Transport

Many practical difficulties exist for the transport of cardamom from the producing areas to the various assembling markets owing to the absence of suitable roads. Transport is both difficult and costly. For instance, the owners of small plantations in the Cardamom Hills have to send their produce in head-loads and incur an expenditure of Rs. 1/12/- per head load of 40 to 50 lb. for transporting the produce for 10 miles down the ghats whereas in the case of lorries, the transport charges come to hardly four annas. Similar difficulties for the transport of cardamoms were also found to exist at Saklaspur and Mercara. Improvement of road communication in these regions would greatly help these small producers in the marketing of their produce.

(v) Technological research

In many countries of Europe, cardamom oil is used for medicinal and industrial purposes. It is only in one or two places in India that some research work has been done regarding the technological possibilities of this crop. The preliminary investigations carried out at the Indian Institute of Science, Bangalore and the Kerala Soap Institute, Calicut have indicated that (1) the oil-content of different varieties of cardamom varies from 3 to 7 per cent of the weight of the dried mature fruit; (2) the outer-coating or pericarp of the cardamom fruits also contains as much as o 2 cent. of the cardamom oil; (3) the oils obtained from both the seeds and the pericarp are identical and have the following specifications:

Specific gravity	-0.936 to O. 938
Optical rotation	
Refractive index	1.4698 to 1.4620
Saponification value	96 to 156
Acid value	0.4 to 1.3

Although the technological possibilities of extracting oil from commercial cardamom are thereby indicated, further progress on commercial utilisation has not been made.

4. Summary of conclusions and recommendations

(i) General outlook

The average demand for cardamom in the world markets is small and is reckoned at 1200 tons annually. Since bulk of this demand is already being met by supplies from India, the scope for further expansion of India's trade in this product is limited. Instead of trying to expand the foreign trade, steps should be taken to retain the position already gained in the overseas markets by maintaining the quality of the cardamoms exported from India.

(ii) Alternative uses for cardamom and cardamom oil

Since cardamom and cardamom oil have only limited uses, research should be conducted to find out alternative uses for these products. The National Chemical Laboratory at Poona and the Council of Scientific and Industrial Research should investigate the possibilities and also subsidise suitable schemes in this connection.

(iii) Need for new research stations

Agronomic and botanical research on the cardamom crop have been inadequate in all the producing areas. Considering the need for scientific aid in these problems, we recommend that two additional cardamom research stations should be opened, one in the Saklaspur region of the Mysore State and another in the Cardamom Hills of Travancore-Cochin. The regional research station at Mysore should study the problems of Coorg also.

(iv) Scarcity of planting material

In many plantations, great difficulty is experienced in obtaining reliable planting material. Early arrangements should, therefore, be made to select suitable sites in the main producing areas and propagate seedlings and disease-free rhizomes so as to meet the requirements of all the planters. A Five-Year Nursery Scheme should be prepared and worked in this connection.

(v) Control of pests and diseases

Experiments conducted at Madras (Singampatti) and Bombay (Sirsi), have found out suitable remedies for controlling thrips and mosaic which take a heavy toll of the cardamom crop in India. The State Departments of Agriculture should give wide publicity to these remedial measures and include these as important items of their extension work.

(vi) Publish all-India crop forecasts

In spite of the importance of the cardamom crop, particularly in the economy of Travancore-Cochin, Mysore and Coorg, reliable estimates of area and production are not available. The normal yield used in the preparation of some of the crop estimates is also unreliable. The Central Government should, therefore, conduct pilot sample surveys to find out the normal yield in all the important producing areas and arrange to publish regular forecasts of area and yield of this crop on an all-India basis.

(vii) Increase consumption in Upper India

The main demand for cardamom within the country is in the markets of Upper India. In order to enable the producers to sell at

cheaper rates and to reduce the costs of distribution it is recommended that specially reduced station-to-station rates should be charged by the railways for transporting cardamom from the producing areas of South India to the distributing centres of Upper India.

(viii) Publicity in foreign markets

The important foreign markets for Indian cardamom are the countries of the Middle East and Europe, particularly Saudi Arabia and Sweden. The India Government Trade Representatives concerned and the special Export Promotion Agency we have proposed in the case of pepper should give wider publicity to the better aroma and greater oil-content of the Indian cardamoms and take all possible steps to help sales promotion in these markets.

(ix) Uniformity in grade standards

The Indian cardamom trade adopts various grades and grade specifications for export purposes. In order to make price quotations comparable, it is necessary to frame standard grades and grade specifications on an all-India basis. Early steps in this direction should be taken under the Agricultural Produce (Grading and Marking) Act. These standards of quality should then be included in the trade contract terms.

(x) Premium for the producers

The producers of cardamom do not as a rule clear the produce or sort it out into different trade classifications. Such cleaning and grading is done only by the merchants. In view of the higher premium obtained for the better qualities of cardamom, it would be more remunerative for the producers if they could themselves undertake to grade the produce before taking it to the auction floors.

(xi) Organising Co-operative Marketing Societies

The co-operative societies engaged in the marketing of cardamom, particularly those at Saklaspur and Mysore, were found to do useful work. For want of better storage and credit facilities the volume of business handled by these societies was comparatively small. The State Governments concerned and the Central Government should provide these facilities and thus encourage the formation of more cooperatives. The facilities may be in the form of loans and subsidies for the construction of warehouses and liberalisation of the rules governing the issue of loans by the societies.

(xii) Regulation of markets

The charges for marketing of the produce which are payable by the producers in many of the markets amount to about 10 per cent of the prevailing market price. By standardising the weights and various market practices and charges, under the provisions of the Regulated Markets Act, it should be possible to increase the margin of profit of the producers. Early steps in this direction should be taken by the State Governments concerned.

(xiii) Organise market-news service

There is need for organising market-news service at least in all the important assembling centres with a view to enable the producers to determine their selling price and derive the maximum benefit.

(xiv) Organisation for development

The central and regional committees proposed for the development of the pepper industry should deal also with the various measures which we have recommended above for developing the cardamom industry in India.

CHAPTER III GINGER (ADRAK)

1. General outlook

Ginger of commerce is the dry product prepared from the green underground stems or rhizomes of the plant (Zingibar officinale). Although the crop is widely cultivated in the tropical countries, bulk of the annual production in these regions is consumed locally as green ginger itself or in the preserved form and only a small proportion of the crop is converted into the dry ginger of commerce. The most important producers of commercial dry ginger are India, Jamaica and Sierra Leone. China also produces large quantities of ginger, but it is mostly as green rhizomes which are used primarily for consumption in the preserved form. In China, this product is not regarded as a spice nor does it for this reason directly compete with the commercial dry ginger of other countries.

The average annual production of dry ginger in Sierra Leone has been found to vary from 1500 to 2500 tons and the Jamaican crop is estimated at 1000 to 1500 tons. With her production reckoned at 10,000 tons, India is the largest producer and the present supplies from all these sources have been found to vary from 12,500 to 14,000 tons.

The pre-war demand for dry ginger in the world marke... was nearly 7,000 tons. As compared to this, the demand during the postwar period has declined by nearly 1,500 tons. The principal sources and the names of the importing countries are given in Table I.

Table I

Distribution of exports of dry ginger from principal sources

(in tons)

Importing	Export from Jamaica		Export from Sierra Leone		Export from India	
countries .	1938	1948	1938	1948	1938	1948
U. S. A	400	650	1,100	650		
Canada	150	150	100			
U. K	700	400	750	600	150	50
Australia	50		50			
Aden			50	1	1,150	900
Arabia					450	500
Others		200	650	50	750	600
Total .	1,300	1,400	2,700	1,300	2,500	2,050

It will be seen that India, Jamaica and Sierra Leone form the main source of supply of this spice both before and after the war. While most of the Western countries such as the U.S.A., Canada, U.K. and Australia imported ginger from Sierra Leone and Jamaica, the African territories, Arabia, Aden and other Middle-East countries preferred the Indian product. The preferential demand for the produce of Jamaica and Sierra Leone is attributed largely to the fact that the ginger produced in these regions is cheaper in price by 20 to 30 per cent and is of better quality having lesser fibre-content as compared to the Indian product. Unless the intrinsic quality of Indian ginger is improved by breeding better varieties, and all possible steps are taken to reduce the cost of production the scope for expansion of our foreign trade in this spice is limited.

2. Position of the industry in India

(i) Some facts regarding cultivation

The most important ginger-growing areas in India are Travan-core-Cochin and Malabar. The preparation of the dry ginger of commerce is also exclusively confined to these areas. To a smaller extent the crop is grown also in parts of Bengal, the Kumaon valleys of the Uttar Pradesh, Bombay, and Hyderabad. In all these areas, however, the crop is produced mainly for its green rhizomes and is not converted into the dry ginger of commerce. The export trade in this commodity thus forms a purely West-Coast industry. In Travancore-Cochin, the main producing centres are in the Kottayam division particularly in the talukas of Muvattupuzha, Thodupuzha, Vaikom, Meenachil, Thalapilly and Kunnathunad. Other main producing areas in the West Coast are in the Malabar district of Madras State where the cultivation is concentrated in the Ernad taluka. In this taluka, Cherur and neighbouring villages are typical growing areas and are particularly reputed for ginger cultivation.

Being a rain-fed crop, ginger is grown generally in areas of heavy rainfall. It requires a rich and well-drained soil for its successful cultivation. The soils most suited for the crop are sandy or clayey loams or the typical red loams and laterites of the Malabar coast. The plant thrives both at sea-level and at an altitude of 3000 ft. as in the Mysore plateau. In the foot-hills of the Himalayas, it is known to grow at an altitude of 5000 ft. But as in the case of pepper, neither very high altitudes nor the coastal regions seem to be favourable for the successful cultivation of the crop. The lower slopes of the western ghats appear to be more suitable for better growth and yield. Being a tropical plant, it also requires a warm and humid climate and considerable shade.

Though ginger is a perennial plant which lasts in the field for more than a year. It is usually cultivated as an annual crop. The crop takes 9 to 10 months for maturity and every year a fresh crop is taken. The plant is propagated vegetatively by means of the underground stems called rhizomes. Ordinarily, only one variety is met with in the different localities but the local varieties are grown year after year.

Before planting, the field is dug-up or ploughed and prepared into long and narrow beds. The beds are heavily manured with cattlemanure and levelled. Seed ginger consisting of small portions

of the underground stems collected from the previous crop is then planted in these beds in small pits made at a distance of about 6—10 inches each way. Planting is done by the end of May or the beginning of June before the commencement of the heavy rains and the beds are covered with a thick mulch of leaves which serves to protect the young shoots from the fury of the monsoon showers and also serves as organic matter when decayed. In about 2 to 3 weeks time the buds shoot up. In July-August, the beds are weeded and further manuring is given to the beds. Generally, 2-3 mulchings and an earthing-up are given. The plant grows to a height of about two feet and develops several lateral shoots in each clump. The underground stems develop and become ready for harvest by December-January. As the crop matures, the aerial shoots begin to dry up and lodge on the ground. There is also yellowing of the leaves. The harvesting is done by digging the whole crop or only portions of the crop according to the needs of the producers for sale in the markets.

The quantity of seed ginger used is generally one candy of 6 cwt. or 672 lb. but very often even double this seed rate is used. With higher seed rates, the yields obtained have also been found to be higher. Under good garden cultivation, the average yield of green ginger is 8—10 fold of the seed rate. But in certain soils having alluvial deposits, the yield is reported to be as high as 40 times which goes to show the immense possibilities of increasing the output of this crop by suitable improvements in agricultural practices.

Ginger is an expensive crop. It requires large quantities of seed material and intensive applications of manure. The cost of tillage operations, weeding and harvesting are also very heavy. Majority of the cultivated holdings are, therefore, small and are below one acre in size.

(ii) Preparation of dry ginger for the market

After digging out, the underground stems are thoroughly washed with water in order to remove the loose soil and dirt sticking to them. These are then kept in the sun for a day or so and then taken to the nearest village markets for sale as green ginger, or adrak. It is in this form that bulk of the crop is marketed in India. For purposes of foreign export only dry ginger is used, the preparation of which is a local craft so far confined to Malabar and Travancore-Cochin. Small quantities of dry commercial ginger are said to be prepared at Keliavasna and Borvia in the Ahmedabad and Kaira districts, respectively, of the Bombay State but the total output is not sufficient to meet even the local demand.

Dry ginger is prepared by peeling off the outer skin present in the green rhizomes and drying them in the sun. In order to facilitate peeling, the harvested produce is soaked in water and kept overnight. The following morning the produce is rubbed well between hands and after cleaning it thoroughly, it is taken out and the outerskin is scraped off with a sharpened bamboo piece and the peeled produce is again soaked in water and cleaned well. After cleaning it is taken out and thoroughly dried in the sun for about a week taking care to turn the whole lot frequently so as to give the produce a uniform drying. On drying, the rhizomes are again rubbed well

between hands in order to remove any outer skin. The dry ginger produced in this manner is known as the 'rough' or unbleached ginger of commerce. Bulk of the dry ginger produced in Travancore-Cochin consists of this quality only.

Another quality of dry ginger prepared at the West Coast is known as bleached ginger. For bleaching green ginger is placed in large shallow cisterns and water let in until the water level in the eistern stands above the produce by about one foot. The entire mass is trampled under feet and cleaned thoroughly of the soil and roots and the skin is also partly peeled off. The process of soaking under water, trampling and clearing the produce is repeated until the produce is thoroughly clear and also free of its outer skin. The peeled ginger is then removed and dipped in a solution containing milk of lime. It is allowed to remain there for some time and is then removed and dried in the sun. This process of dipping in lime water and drying in the sun is continued until the product receives a uniform coating of lime and assumes a bright colour. Dry ginger prepared in this manner is known as 'limed ginger' or bleached ginger. The bleached ginger is in great demand in the countries of the Middle-East and also within India while the unbleached product is in great demand in the European markets.

When prepared in this manner, the yield of dry ginger, bleached or unbleached, obtained from green ginger works out to 20 to 24 per cent. Bleaching is also done by fumigating ginger with sulphur, but this practice has now been given up since sulphur has become too costly and the importing countries have prohibited the presence of sulphur dioxide in the commercial samples.

(iii) Area and production

Regular forecasts of the ginger crop are published in India. According to these forecasts the acreage and production of the crop in the different States during 1951-52 were as shown in Table II.

Table II

All-India estimate of area and production of dry ginger for 1951-52

State	Area in acres	Production in tons
Trayancore-Cochin Madras (Malabar & South Kanara) Uttar Pradesh Himachal Pradesh Hyderabad Bombay West Bengal Mysore Coorg Others	21,451 13,100 4,000 2,014 1,804 1,210 1,040 38 17	7661 4410 2960 973 470 551 600 4 6 586
Total	46,228*	18,221

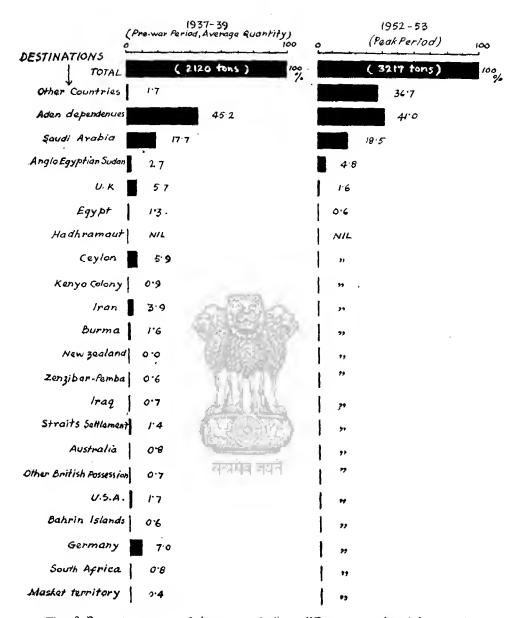

Fig. 18. Percentage export of ginger from India to different countries of the world

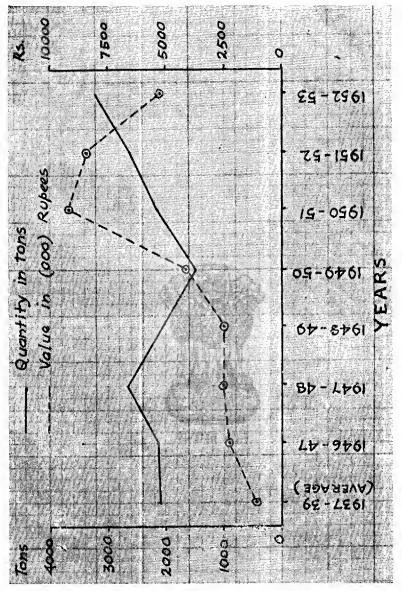

Fig. 19. The trend of exports of ginger from India

सन्त्रपंत्र नवने

The total area under the crop during 1951-52 amounted to 46,228 acres. As much as 46.4 per cent of this acreage was distributed in Travancore-Cochin and 28.3 per cent in the Malabar district of the Madras State. Between these two regions, three-fourth of the acreage under the crop was distributed. Other growing areas are distributed largely in Uttar Pradesh, Himachal Pradesh, Hyderabad, Bombay and West Bengal. The ginger crop grown in Mysore, Coorg and other areas was comparatively much smaller.

The total production from all these areas during 1951-52 has been estimated at 18,221 tons. As already stated, in most of the producing areas the entire crop is used locally as green ginger or adrak and the commercial dry ginger is prepared largely at the West Coast in the two regions of Travancore-Cochin and Malabar. These two regions together accounted for a total crop of 12,071 tons. Out of which 20 per cent of the crop is preserved as green ginger for seed purposes and the producers retain another five per cent of the green produce for purposes of medicine, and other domestic uses. The remaining 75 per cent of the West Coast crop amounting to 9,053 tons of dry ginger constitute the marketable surplus available for export and internal distribution.

During 1952-53, the estimated acreage under the crop amounted to 49,458 acres and the total production to 16,615 tons. The supply of commercial dry ginger from the West Coast during the season is estimated at nearly 8,000 tons. The production shows a decline of 1,000 tons as compared to that in the previous year. This is largely due to the unfavourable weather conditions which prevailed during the cropping season particularly in Travancore-Cochin (vide appendix XVIII).

Uttar Pradesh grows ginger over a fairly large area and nearly 4,000 acres are put under this crop annually in this State. The total production in this State has been estimated at 14,800 tons of green ginger or 2,960 tons in terms of dry ginger. As this State has not been included in the preparation of all-Indian crop forecasts, arrangements should be made for its inclusion so as to make the forecasts more complete.

As ginger deteriorates in quality on storage, it is marketed immediately after curing and drying. The main marketing season is during the months of January, February and March.

(iv) Export trade

The annual exports of dry ginger from India to the overseas markets during 1952-53 were the maximum and amounted to 3,217 tons. More than half of the foreign trade is with the countries of the Middle East, the most important being Aden and dependencies which accounted for 41.0 per cent of the total export trade. Both before and after war, this country has been our most important customer. The exports to this country are made through the Bombay port and consist mostly of bleached ginger received from the Malabar coast. Saudi Arabia comes next and accounts for 18.5 per cent of the export trade. Other importing countries are South Africa, Ceylon, Anglo-Egyptian Sudan, Egypt, Iran, the U.K., and the U.S.A. As compared to the quantities exported before the war, the present exports to

Saudi Arabia, Ceylon, Egypt and South Africa show an increase. The exports to the U.K., the U.S.A., Aden and dependencies and Iran have, however, fallen from the pre-war level. The scope for export promotion in these countries should be investigated by the Indian Government Trade Representatives abroad.

The exports of dry ginger to the overseas markets take place through the ports of Bombay and Madras. By far the largest quantity is, however, shipped from the Bombay port.

The pre-war value of exports averaged Rs. 114 lakhs which increased during the war to Rs. 214 lakhs and has risen up to Rs. 521 lakhs at the present time. The increase in total value has been largely due to the post-war rise in the prices of this spice. Since last year the prices have declined so that in spite of the larger quantities exported during the current year the value of the total exports have fallen as compared to that of last year (vide appendix XIX).

(v) Qualities

The underground stems of dry ginger develop many lateral branches and are shaped like the fingers of a hand when harvested. As there is a special preference for such hands and fingers in the foreign markets, merchants prepare dry ginger in three export qualities, B, C, and D, consisting of three fingers, two fingers and pieces, respectively. In the European markets, B and C qualities are in demand mixed in the proportion of 20:80. The D grade consisting of pieces is exported to other countries and is also utilised for internal consumption.

In internal trade, there are distinct qualities recognised according to the areas of production. The produce of Travancore-Cochin is marketed as Cochin ginger. In Malabar, there are three qualities of which the Chernad quality is considered to be the best. It is reddish-brown in colour, the rhizomes are big in size and comparatively less fibrous. Annually about 500 tons of this quality are produced. The second sort known as Ernad ginger represents the produce of the Ernad taluka of the Malabar district. The rhizomes of this quality have no special colour; they are smaller in size and are more fibrous. The third type known as the Wynadan is produced in the uplands of the ghats in the Wynad taluka of the Malabar district and this quality is considered inferior mainly on account of its greater fibre-content.

All these clearly show that the trade has clearly distinguished the quality characteristics of different types of ginger produced in the country. But no attempt has so far been made to prepare uniform grades and grade specifications for this produce on an all-India basis. The framing of such grades and grade standards will greatly facilitate the business transactions.

Ginger for export purposes is packed in single new gunny bags. 115 to 160 lb. of the product are filled in each bag. Along with standardisation of the grades, standards for packing should also be prescribed for export purposes.

Fig. 20. Commercial type of dry ginger

Fig. 21. Ginger plant with fully developed rhizome (Malabar district)

सन्त्रपंत्र नवने

Prices

The prices of commercial dry ginger have generally improved during recent years as may be seen from the quotations at Cochin. From a pre-war level of about Rs. 7 per maund the prices of ginger increased to a maximum of Rs. 164 per maund in 1949-50. Since then, ginger prices have declined. The present prices stand at Rs. 57 per maund but are still seven times more than the pre-war level of prices (vide appendices XX, XXI and XXII). As compared with other spices and food articles, the increase in the price of ginger has not been abnormal. It has been generally keeping pace with the upward trend in the post-war prices.

Both bleached and unbleached qualities are exported but as these two qualities are prepared for different markets, the prices of these two qualities are not inter-related and appear to be guided entirely by the demands of the consuming markets. For instance, in some of the pre-war years, it has been noticed that in spite of its higher bleaching costs, the produce did not receive any premium over the unbleached product.

Though actual costs of cultivation are not available, most of the witnesses who gave evidence before us stated that the present prices of this product are reasonable and that if this minimum price is assured, production would be maintained. More than any other factor, stability in the market price of this crop seems to be the determining factor in extending the cultivation and production of this crop.

(vii) Assembling and distribution

The main assembling markets for dry ginger in Travancore-Cochin are Alleppey and Cochin. The arrivals at Alleppey which amount annually to 2,000 tons, are mostly the produce of Palai and Ponkunnam while the produce arriving at Cochin is mostly obtained from Moovathupuzha, Thodupuzha and other neighbouring areas. In the Malabar district the most important assembling market for commercial dry ginger is Calicut. Almost the entire produce from the talukas of Walluvanad, Ernad and Wynad finds its way to the Calicut market and is distributed from there.

The arrivals in these markets take place mainly during the months of January to March which is the main marketing season for the crop. As the produce cannot be stored for large periods, it is exported immediately, depending upon the demand and availability of shipping space.

Like pepper, ginger is also the most important spice of the West Coast. The agencies engaged in the marketing of pepper carry on the trade in ginger also. After converting the green ginger into commercial dry product, the producers themselves carry small lots to the interior markets and make outright sale to the village merchants who deal in these hill products. When sufficient quantities are purchased by these village merchants dealing in hill produce, they transport it to the assembling markets at Alleppey or Cochin in the case of Travancore-Cochin produce and to Calicut in the case of the Malabar produce. At these assembling markets, the produce is sold to the commission agents from whom the shippers and exporters by and export.

128 I.C. of A.R.

Here the commission agents play an important role and the ginger trade is mostly in their hands. They store ginger in their godowns for which no godown rent is charged. They also advance money to the village merchants to the extent of 75 per cent of the market value of the produce for which 9 to 12 per cent interest is charged. In addition they make deductions on account of (i) discount on sale (ii) commission (iii) brokerage (iv) charity and (v) miscellaneous expenses. All these are deducted from the sale proceeds at the time of final settlement of accounts. These work out to nearly 20 per cent of the market value of the produce.

The village merchants thus realise about 80 per cent of the value of the market price. The incidental charges incurred by them in transporting the produce from the interior markets to the commission agents in the assembling market are generally borne by the village merchants themselves. But they indirectly realise this amount in many cases from the primary producers by manipulating the weights, etc. The merchants make also unauthorised deductions on account of dust and other refraction to the extent of 4 to 6 per cent of the weight of the produce. Even if cleaner produce is marketed such deductions are made and the producers, therefore, often lose the incentive for selling better quality produce. These defects can be remedied only by organising regulated markets for this product in import centres.

The produce changes hands at least three or four times and with each change the margin of the producer is reduced. The number of links in the chain could be reduced if the sale is attempted by the producers themselves on a co-operative basis. The satisfactory working of the District Produce Sale Society of Malabar at Calicut and Vengara indicate that there is great scope for employing the co-operative method for the sale of this and other hill produce of the West Coast. The authorities of this society particularly at Vengara, the main primary market for Ernad ginger, stated that the godown space provided was not adequate and if larger godowns could be constructed they could increase their turnover. All facilities should be given by the Centre and the respective States to provide adequate godown space to such primary co-operative societies and thus encourage co-operative marketing of this product.

3. RESEARCH, TECHNOLOGY AND DEVELOPMENT

(i) Regional research stations

From the point of view of international trade, the more urgent need of the ginger industry in India is to improve the quality of the local produce by evolving a fibre-free product by introduction, cross-breeding, and/or selection. The Jamaica and Sierra Leone products are superior to the Indian product in this respect and we cannot compete with these countries until we improve the quality of our product. No scientific research has so far been carried out to achieve this object. We should also step up our yield per acre and thus bring down the production costs so as to offer competitive prices for our products. As all these involve both fundamental and systematic research, there is need for opening research stations in all important producing areas.

(ii) Supply of seed rhizome

Generally, cultivators retain adequate quantities from their previous crop for purposes of seed. Very often these are found to be diseased and the cultivators experience considerable difficulty in getting reliable planting material. We, therefore, suggest that arrangements should be made to establish a large number of seed multiplication farms and for supply of quality seed material.

(iii) Better methods of storage

The quality of ginger stored in gunny bags deteriorates in 5 to 6 months. Research should be conducted to improve the keeping quality of this product by improving the methods of storage. Various methods of preparing commercial dry ginger also require careful investigation and study.

(iv) Pests and diseases

There are no serious pests attacking the ginger crop but the 'softrot' sometimes causes considerable loss. The affected plants become pale and the tips turn yellow followed by the wilting and drying of the leaves. The shoots and rhizomes are also gradually affected and further production of rhizomes is stopped. This disease is prevalent in damp and badly drained soils and the loss is heavy in places of heavy rainfall. The soil and seed are both affected and being a vegetatively propagated crop they carry the infection from one crop to the next. The damage is caused mostly by an organism belonging to the Pythium species. The remedy advocated by the Agricultural Department against this disease is the use of 0.05 per cent mercuric chloride for treating the rhizomes before storing as seed as well as at the time of planting. Apart from being a poisonous chemical which is not safe to handle, the remedy has not been reported to be fully effective. Experiments with colloidal copper and chestnut-compound appear to give more promising results. Another disease noted on ginger is known as 'varmicularia' where the leaf blades become covered with yellowish and brownish spots and gradually dry up. Spraying with Bordeaux mixture is indicated in such cases.

Among the pests, mention may be made of the turmeric shoot borer. Suitable remedial measures for combating this pest should be found out.

(v) Technology

In the foreign countries, large quantities of ginger are utilised for the extraction of ginger essence and oil. As great demand exists for such products in India itself, facilities should be given to set up such industries in the country and encourage the export of these manufactured products to the overseas markets.

4. Summary of conclusions and recommendations

((i) General outlook

As compared to the commercial qualities of dry ginger exported from Jamaica and Sierra Leone, the Indian product is more fibrous and is considered to be of inferior quality. The prices of the Indian

ginger are also 20 to 30 per cent more than those of the two foreign qualities. Nearly two-thirds of the world demand is met by supplies from the former two countries and the rest is contributed by India. Further expansion of India's foreign trade in this spice depends largely upon the improvement in the intrinsic quality and costs of Indian ginger.

(ii) Need for starting new research stations

Although some of the diseases of the crop have received attention in some of the States, no botanical improvement has so far been undertaken particularly with a view to improving the local types of ginger. We recommend that regional research stations should be opened in typical ginger-producing areas for evolving a better type of ginger having less fibre-content and finding out other improved. agronomic practices.

(iii) Credit facilities during cultivation season

Ginger is an expensive crop to grow and although the cultivators are greatly in need of financial assistance during the cultivation season, adequate credit facilities are not available. It is, therefore, recommended that the Governments of the States concerned and the Central Government should assist in removing all credit restrictions in the working of cooperative societies and make available adequate production credit. There is considerable scope for expanding production if such seasonal credit facilities are provided.

(iv) Crop estimates

The forecasts of area and yield of the ginger crop do not include the figures for States like Uttar Pradesh where nearly 14,800 tons of green ginger equivalent to 2,960 tons of dry ginger are produced in nearly 4,000 acres. These and other producing States should be brought under the reporting regions and the forecasts made more comprehensive. It should, however, be stated in the forecast that bulk of the local production is consumed as green ginger in most of the producing areas, and the conversion of green ginger into the dry form for export purposes is concentrated in the West Coast regions of Travancore-Cochin and Malabar.

(v) Uniformity in grade standards

Dry ginger is exported both in bleached and unbleached forms. To obtain price quotations on a comparable basis and create better confidence in the foreign buyers, it is necessary to frame suitable grade standards for this product on an all-India basis. Early steps in this direction should be taken under the Agricultural Produce (Grading and Marking) Act. These standards of quality should then be included in the trade contract terms which should provide also facilities for arbitration in India in case of disputes between the parties.

(vi) Trend of foreign exports

Although the post-war exports showed an increase over the prewar period, recent exports have shown a decline particularly to the U.S.A., the U.K., Aden and dependencies and Iran. The causes of this decline and the scope for export promotion in these countries should be investigated by the Government of India Trade Representatives abroad.

(vii) Co-operative marketing

The cooperative agency plays a very insignificant part in the marketing of dry ginger. The main difficulty that stood in the way of the development of some of these societies did not provide for adequate storage facilities. Necessary financial assistance should be given by the Central and State Governments to these cooperatives for the construction of warehouses in all important marketing centres.

(viii) Regulation of markets

As in the case of other agricultural commodities, there is no uniformity in the system of levying market charges in the case of ginger also. Standard weights are not also always used. The producers' share of the prevailing prices could be increased by extending the operation of the Regulated Markets Act to this article also in all important markets in the West Coast.

(ix) Fumigation at the ports

In order to reduce insect infestation in the products exported from India, arrangements should be made for their proper storage and fumigation at the ports of shipments.

(x) Market-news service

The producers in most of the ginger-producing areas are unable to obtain the maximum prices for their produce as they are not aware of the prevailing conditions in other markets. It is, therefore, necessary to organise a market-news service and disseminate up-to-date information regularly by means of radio-broadcasts, bulletins, etc.

(xi) Organisation for development

The central and regional committees proposed for the development of pepper should deal also with the various measures which we have recommended above for developing the ginger industry in India.

सन्त्रपंत्र नवने

CHAPTER IV

TURMERIC (HALDI)

1. GENERAL OUTLOOK

Like ginger and cardamom, turmeric is also grown only in the tropical countries. Its cultivation extends from India to Indo-China. East Indies and part of China. But excepting India very little information is available about the production and trade of this commodity in other parts of the world.

2. Position of the industry in India

(i) Some facts regarding cultivation

Turmeric known as haldi in Hindi and manjal in Tamil and Malayalam, is used as an important condiment almost in every Indian home and has been under cultivation in India from very ancient times. The crop grows from sea-level to an altitude of 4,000 ft. In higher altitudes, it is met with in the wild form both along the eastern and western ghats. The soils most suited for turmeric cultivation are sandy and clayey loams. The crop requires proper tillage and careful cultivation. It cannot stand water-logging or alkalinity in the soils. It is grown both under irrigation and as an unirrigated crop. On the West Coast, turmeric is cultivated solely with the help of the monsoon rains.

Varieties. There are no sharply distinguished varieties under cultivation but some types grown in certain localities are reputed for their colour. The Malabar variety is reputed to have better medicinal properties particularly for cold and catarrh while the types grown near Poona and Bangalore are specially esteemed for the depth of the The wild turmeric is distinguished from the cultivated varieties as Curcuma aromatica because of the considerable fragrance emitted by some of these stems. Curcuma amada is another type of turmeric grown in many parts of the east coast where it is known by the name of mango-ginger. Its resemblance in taste and smell to green mangoes when tender has probably given rise to this local name. The rhizomes of this variety of turmeric are much thinner than other varieties and are whitish in colour instead of being vellowish as other varieties. The mest popular variety cultivated for commercial purposes is however Curcuma longa.

Cultivation. The crop is propagated vegetatively by means of its swollen under-ground stems known as corms. The crop requires a fine tilth and heavy application of manure. The preparatory cultivation consists of ploughing the field six times, breaking the clods and removal of stubbles, roots and weeds from the surface of the field. Cattle manure is then applied at the rate of about 40 cartloads per acre and the field prepared into narrow beds with facilities for irrigation and drainage. During April to July turmeric corms (underground stems) are planted in these beds 6 to 9 in. apart in the furrows and 16 in. apart between the furrows. After planting seed material, the beds are levelled and a thick mulch of leaves is applied on it. Quick-growing vegetables and root-crops like Colocasia and yam are also sometimes planted in between the beds. The corms send forth aerial shoots above the ground in about a

month's time and make rapid growth. One or two hoeings and weedings are given and the beds are earthed-up along with the harvesting of the minor vegetables and root crops at the close of the south-west monsoon. By November, the leafy growth of the turmeric crop is fairly complete and the corms below begin to thicken and develop uniformly deep colour. About February the leaves begin to turn yellow and dry up one by one which is an indication of the maturity of the under-ground stems or corms. Harvesting commences in March and continues till the end of April.

Harvest. Harvesting of turmeric has to be done with great care. The whole clump has to be lifted up without injuring the corms which consists of both primary and secondary branches known as 'fingers' as well as the main thickened portion known as the 'bulb'. The leaves and roots are then cut off and the bulb and fingers separated from each other. Very small quantities are marketed in this raw form but bulk of the turmeric crop in India is marketed as dry cured turmeric.

The quantity of seed turmeric used for planting purposes varies from 750 to 1500 lb. per acre and the average yield of green turmeric is generally 8 to 10 fold. Much heavier yields are however obtained under more intensive methods of cultivation.

(ii) Preparation of commercial turmeric

The green turmeric has to be cured properly before the commercial product can be obtained. Curing consists mainly of boiling and drying the harvested produce and giving it a polish for improving its appearance.

After harvest, the raw green turmeric is heaped up and covered over with turmeric leaves and kept in this condition for some time. The entire produce is then transferred to an earthen pot or large iron pan and the vessel is filled with water, the water level standing 2-3 inches above the level of the turmeric. After covering with dry turmeric leaves, the vessel is boiled under direct fire. When the rhizomes turn soft to touch, these are removed from the pan and thinly spread out and dried in the sun. After 5—7 days of drying, the produce becomes fit enough for storage and sale. After it is quite dry, it is cleaned to remove roots and other parts and then rubbed well between hands. It is also polished by means of special appliances. The produce is then sorted out into fingers, bulbs and splits and also graded into large and small sizes according to the requirements of particular markets.

The recovery of cured commercial turmeric from the raw green turmeric varies from 15 to 25 per cent.

(iii) Area and production

Unlike the cash crops included in the terms of our reference, turmeric has no special importance in the agricultural economy of the West Coast. The acreage and production of this crop are small in these regions and the trade in this product is also relatively insignificant.

The principal turmeric-growing areas in India are the East Coast distributed mainly in the two States of Andhra and Orissa. To a smaller extent, the crop is grown also in parts of Bombay and Hyderabad. In the Andhra State, turmeric-growing is concentrated.

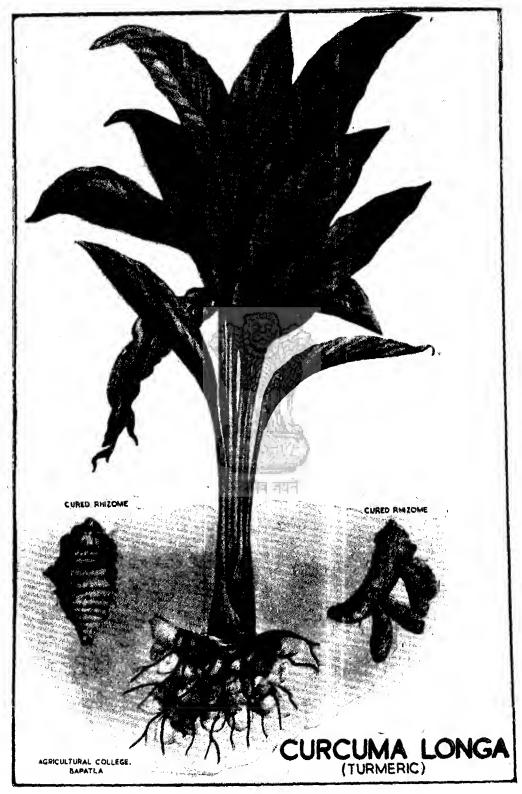

Fig. 22, Curcuma longa (turmeric) plant and rhizomes

Fig. 23. Curcuma Lomestica (Courtesy C.S.I.R.)

in the Guntur district particularly at Duggirala. By far the largest amount of the commercial supplies are obtained from this source. Other areas of large-scale turmeric cultivation in the State are the districts of Cuddappah, Kistna, West and East Godavary, while Tiruchirapally, Salem and Coimbatore districts of Madras are also important for this crop. The production in the west coast region is insignificant. (vide appendix XXIII).

Orissa is the next important growing-area for turmeric in India, the centres of concentrated production in this State being the districts of Ganjam, Phulbani and Koraput. In Bombay, the main centres of turmeric production are in Gujerat, Thana and Khandesh districts. The Sangli and Kolhapur areas also produce sizable quantities of the crop.

Among the other States which are important for this crop, may be mentioned Uttar Pradesh, Madhya Pradesh, Mysore, West Bengal, Vindhya Pradesh, Rajasthan and Punjab.

Regular forecasts of the turmeric crop in India are not published. But from the information obtained from official sources, the area under and the production of turmeric crop in the different States of India have been estimated as shown in Table I.

TABLE I

Area and production of turmeric in different States of India

State	Area in acres			Production in tons		
	1949-50	1950-51	1951-52	1949-50	1950-51	1951-52
Bombay	10,212	10,212	10,212	8,800	8,800	8,800
Madhya Pradesh	2,151	2,372	2,518	1,306	1,468	1,564
Madras	54,125	53,685	53,685	69,800	72,300	72,300

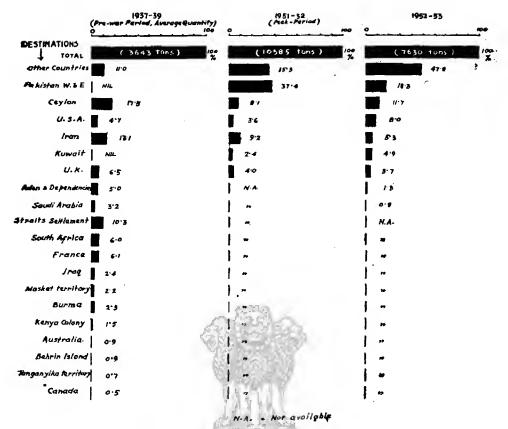

Fig. 24. Percentage expert of turmeric from India to different countries of the world.

बकायन नगरी

On an average, turmeric crop covered an area of 1,35,365 acres during the triennium ending 1951-52, and total production of dry cured turmeric from those sown area has been estimated at 1,10,542 tons which works out to an average yield of 1,978 lb. or nearly one ton per acre.

The average yield has been found to vary from 2,500 to 4,000 lb. in Salem, Tiruchirapalli and Tanjore while in Guntur and Kistna, the yield is as high as 5,000 lb. of cured product. In Orissa, the average yield in the main producing area of Ganjam is estimated at 2,500 lb. while in other districts only one-third of this quantity is obtained. Such wide variation in the yield of this crop is due to differences in cultural practices. But this clearly indicates that with proper care and attention, there is ample scope for increasing the yield of this crop.

The acreage and production of turmeric have shown an upward trend in recent years. The total acreage under the crop increased from 1,31,129 acres in 1949-50 to 1,38,739 acres in 1951-52 representing a rise of nearly eight per cent. During the same period, the total production rose from 1,16,155 tons to 1,22,383 tons representing an increase of nearly six per cent. The increase in area has largely occurred in the Orissa State, particularly in the agency tracts. In Madras, the acreage under the crop has remained more or less the same but higher prices prevailing during this period have stimulated intensive cultivation of the crop and have resulted in larger out-turn during the period.

The crop is harvested in the months of February to April. Immediately, thereafter, the curing operations commence and the marketing of the produce also begins. As already stated, the produce is classified by the trade into two main qualities, namely, 'bulbs' and 'fingers'. It has been estimated that nearly 75 per cent of the production in Orissa State and 20 per cent of the crop in the Madras State consists of 'finger'-turmeric while the remaining quantities in these States are marketed as 'bulb'-turmeric. The 'finger'-turmeric is considered to be of better quality and fetches a premium.

(iv) Export trade

There are no imports of turmeric into India from any other country. India exports annually to many overseas markets. While the average annual production amounted to 1,19,542 tons, the exports of cured turmeric from India to the foreign markets during 1951-52 amounted to hardly 10,585 tons representing only eight per cent of the total crop. The rest of the crop amounting to nearly 92 per cent of the annual production is retained as seed and for domestic consumption and distributed in internal trade which has, therefore, assumed great importance in the case of this crop.

Turmeric trade has been depressed since long and this industry does not seem to have seen bright weather for many seasons past. But since world war II, there has been an improvement in the situation both in the quantities exported and in prices. During the prewar period, the average annual exports of dry cured turmeric were of the order of 4,000 tons only. There was a slight increase in this quantity during war but has more than doubled itself at the present time (vide appendix XXIV). The exports during 1951-52 amounted to 10,585 tons. The foreign exports take place mainly through the

Bombay port and are largely controlled by the members of the Kirana Merchants Association and their brokers in the Mudi Bazaar.

The principal importers of Indian turmeric are Ceylon, South Africa, Îran, Âden and dependencies, the U.S.A. and the U.K. The off-take of Ceylon was 639 tons before the war but has increased to 800 tons at the present time representing an increase of nearly 25 per cent. Iran is the next important customer. This country imported 478 tons of turmeric from India before the war but her post-war exports have increased to 657 tons representing an increase of 37 per cent. The exports to Aden and dependencies have increased from 182 tons before the war to 417 tons at the present time representing an increase of 129 per cent. Similar upward trend has been noticed in the exports to the U.S.A. also. The pre-war American demand amounted to hardly 172 tons which has increased to 560 tons representing an increase of nearly 225 per cent. Canada is comparatively a new comer. Before the war, the share of this country in the Indian exports amounted to hardly 19 tons but has increased at the present time by nearly five times. The demand from the U.K. has been more or less steady both before and after the war. Besides these countries, Indian turmeric is at present exported to many other destinations also. Although the off-take of these individual countries is small, these changes in the direction of trade are important and indicate the scope for expanding our world trade in this commodity. Although the exports have increased in recent years, these form less than 10 per cent of the annual crop produced in India and the remaining quantities are all utilised for internal distribution.

There is no definite periodicity in the case of turmeric exports. The quantities exported have been more or less uniform in different months of the year.

There are two qualities of turmeric which are used in the foreign export trade, viz. 'fingers' and 'bulbs'. The European markets prefer the 'fingers' while the 'bulbs' are exported mostly to the countries of the Middle-East. Besides fingers and bulbs, a third quality is also prepared and is known as the 'splits' or mixed. But this quality is mostly used for internal distribution. The growers do not undertake any grading work. They merely sort out the produce into fingers and bulbs and it is the merchants who prepare a uniform produce for export purposes. The merchants prepare the stuff according to the purpose for which it is to be used. The chief factors of good quality in turmeric are a deep yellow colour, hardness, metallic sound, aroma and pungency.

In spite of the well-defined quality characteristics which exist for turmeric such as colour, hardness, metallic sound, aroma and pungency, there are no standard grades and grade specifications for this product. The contract terms adopted by the trade are also not uniform and are based on the terms prescribed by the American Spice Trade Association of New York or the Produce Brokers Association of London. Exports take place in gunny bags which appears to serve the purpose well. The capacity of these bags is generally 140 lb. But with greater uniformity in grades and grade standards and in the packing adopted for export purposes better confidence will be created in the foreign markets.

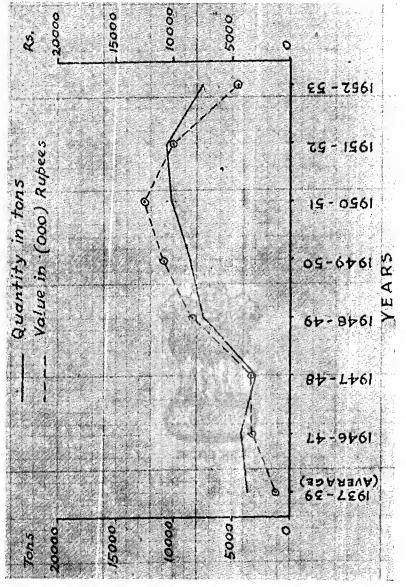

Fig. 25. The trend of export of turmeric from India

सन्त्रपंत्र नवने

(v) Value of exports

Like the quantities exported the value of exports has also steadily increased since world war II. The pre-war value of exports varied from Rs. 10 to 19 lakhs which increased to Rs. 32—35 lakhs immediately after the war. It has increased further subsequently and during the last few years, the total value of turmeric exports from India has amounted to over one crore of rupees annually as may be seen from the following:

Value of turmeric exports

1949-50	•••	***	••••	Rs. 1·10	crore
1950-51	•••	٠		,, 1.25	"
1951-52	•••		•••	" 1·00	,,

The maximum value which was realised during 1950-51 amounted to Rs. 1.25 crores. With the growing demand for this product in the world markets, there is scope for enhancing the quantity and value of these exports. One of the urgent steps that should be taken in this connection is to give better publicity to these products in the foreign markets and to ensure the quality of our foreign exports.

(vi) Internal trade

Unlike other spices and condiments, only a small proportion of the annual turmeric crop is exported from India to the foreign countries. The quantity exported amounts to hardly less than 10 per cent of the total crop produced in India. Bulk of the remaining supply is all utilised within the country and distributed in the north Indian markets. Haldi (turneric) is an indispensable item in every Indian home. With the growth of population, the demand for this condiment has also grown:

Out of an annual production of 1,19,542 tons, 20 to 25 per cent are retained by the producers as raw turmeric for seed and domestic consumption and only the balance amounting to 90,000 tons is available as marketable surplus. Leaving 10,585 tons or nearly 11,000 tons which are exported to the foreign countries, the remaining 79,000 tons are utilised for distribution within the country. The quantity used in internal trade is by far the largest and amounts to nearly seven times more than what is exported outside the country. The produce moves from the producing areas in Andhra, Madras and Orissa States to the distributing markets at Nagpur, Bombay, Calcutta, Kanpur, Delhi, Amritsar and Shalimar. Besides these inter-State movement considerable quantities enter local trade, within the States.

By far the largest quantity entering internal trade, is transported by rail. Nearly three-fourth of the despatches from Madras and almost the entire quantity from Orissa are moved by means of this transport. The arrivals into Bengal and Bombay are by means of coastal steamers.

(vii) Uses

Turmeric is used in various forms in India. It contains a yellow dye 'Curcumin' which is used for colouring textiles like cotton, wool and silk. Old turmeric is preferred for this purposes as it gives a deep and fast colour. It is also used in small quantities by the rice-milling industry in order to disguise the spots on the rice grains. Its use as a colouring material has been reported in the paints and varnishes industry also. With the availability of cheaper, synthetic dye-stuffs, the demand from these sources has lessened.

Turmeric is also used in preparing medicinal oils, ointments and as a preservative. The burnt fumes of certain varieties of turmeric particulary the 'fingers' of the West Coast are said to be a specific remedy for relieving the common cold and catarrh. Both raw and cured turmeric are used against skin diseases and itches. It is also one of the principal cosmetics used by Indian women from ancient times and is an auspicious symbol in many ceremonies.

By far the largest quantity of turmeric is, however, utilised as a condiment. It is used in this form daily in almost all households in India particularly in many vegetable meat and fish preparations. Turmeric is an important ingredient of all curry powders which are exported to the foreign countries. With the growing demand for curry powder in the foreign markets, the demand for turmeric is also likely to go up.

(viii) Prices

Bombay and Calcutta are the two important markets for turmeric in India. The average annual prices prevailing at these two markets give a correct indication of the trend of prices of the product (Table II).

Average annual prices of cured turmeric in some important Indian markets (rupees per maund)

Year	Bombay		Calcutta	
1541	Rs.	As.	Rs.	As
1939	11	- II	12 11	<u> </u>
1940	9 8	_ 11	8	
1941 1942	10	_ ıı	ğ	_
1943	18	- 9	16	
1944	15	- 7 l	15	
1945	15	→ 15	17	
1946	29	2	26	_
1947	40	13	38	_
1948	45	3	44	I
1949	45	— 13	47	— I
1950	46 28	6	49	
1951	28	o	23	
1952	28	- 0	22	
1953	28	— •	22	

As compared to the pre-war figures, the prices of turmeric have generally improved during the post-war period. This general improvement in the price level is noticed both at Calcutta and at Bombay which are the most important distributing markets for this product in India. From the low level of Rs. 8 to Rs. 12 per standard maund prevailing for the produce at the commencement of the world war II, the prices steadily increased and touched nearly Rs. 30 towards the close of the war-period. In subsequent years, the prices further increased and stood at Rs. 46 to Rs. 50 representing an increase of nearly five times over the pre-war level. This maximum rise was noticed during the year 1947—1950 (vide appendices XXV—XXVIII).

Since 1950, the prices of turmeric have declined and in 1952-53 seem to have stabilised at Rs. 22 at Calcutta and Rs. 28 at Bombay. The present depression has been brought about partly by the larger supplies received during this period and partly also due to the weak demand from the foreign markets. As compared to the 1947-50 figures, these price levels are low but are not lower than the prewar level of prices. The prices are still nearly 2 to 3 times more than the pre-war price levels which condition is nearly in keeping with the general rise in the post-war prices. In recent months, the prices have shown some recovery. As there is a steady demand for turmeric in India, there is no marked seasonal variation in the price of this product. From April to October, however, the prices of turmeric remain below normal in some years due mostly to the larger supplies available during this season. From November onwards, the prices show an increase and continue the upward trend up to March. This seasonal variation is attributed to the reduced stocks and larger foreign exports during this period.

(ix) Assembling and distribution

The important assembling markets for turmeric are in Andhra, Madras and Orissa States which are the principal sources of supply of this commodity. In Andrea the most important assembling centre is Duggirala while Madras, Erode, Salem and Cochin are the main centres in Madras State. In Orissa, the main assembling markets are Berhampur and Parlakimedi in the Ganjam district and Jeypore and Nawrangpur in the Koraput district. The Bombay produce is assembled mostly at Sangli and in smaller quantities at Tasgaon, Kolhapur, Takari and Karad.

As already stated the main distributing markets in India are Madras, Bombay, Berhampur, Nagpur, Delhi, Kanpur, Amritsar and Shalimar.

Turmeric is marketed in three different ways. These are (1) direct sale by the growers, (2) sale by commission agents and (3) sale by village merchants to wholesalers. Generally, however, the trade is in the hands of the commission agents. Often the growers go to the commission agents and seek their aid. The buyers also go to these commission agents and make use of their services. The commission agents arrange for conducting auctions, supervise weighing, etc., settle the amount due and complete the transactions and charge a commission from both the parties at the rate of one to two per cent of the value. In most of the transactions, the produce

was found to change hands 3 to 5 times and the grower has been found to realise 54 to 80 per cent of the prevailing market prices. The majority of the producers being poor they take loans from the village merchants and commission agents and are indebted to them. Under these circumstances, the bargaining power and the margin of profit of the producers are curtailed.

The role of the co-operative agencies in the marketing of turmeric is almost negligible. This situation is exploited both by the village merchants and by the commission agents to whom the producers sell their produce at a price generally fixed by them. The absence of standard weights and specified market charges give further scope for manipulation of these agencies and reduce the returns of the producers.

3. RESEARCH, TECHNOLOGY AND DEVELOPMENT

(i) Opening new research stations

Although Madras so far constituted the most important source of supply of turmeric in India, very little attention has been paid for the scientific development of this crop. The tenali or the duggirala type of turmeric grown in this region is reputed for its better qualities. No systematic attempt has, however, been made to study this crop in its native habitat or to propagate it in a systematic manner. There are also many cultural and manurial problems which have to be tackled. To add to these, the turmeric crop in these tracts is prone to the attack of pests and diseases which are locally known in Telegu as lambodi tegulu, pogachuru tegulu, and tateku tegulu. No regular attempt has been made to find out suitable remedial measure for these diseases and pests or to supply disease-free seeds for planting purposes. All these require systematic investigation at a regional research station.

Arrangements should also be made at this station for the multiplication and distribution of good type of seed-turmeric to the cultivators and to find out suitable methods for the preservation of the seed material.

The Turmeric Research Station started at G. Udayagiri in the Orissa State under the auspices of the Indian Council of Agricultural Research, has carried out investigations on many local problems in Orissa. Some of the results obtained at this Station could be used with advantage in other areas also.

(ii) Improved type of furnace for curing

The experiments conducted at the Turmeric Research Station, Orissa have shown that in the local type of furnace used for curing turmeric, nearly 65 maunds of fuel are necessary for curing 100 maunds of raw turmeric and that in a day of eight hours nearly three maunds of raw turmeric could be cured. The improved local type evolved at the station used only 50 maunds of fuel for the same quantity. The quantity of raw turmeric that can be cured per day of eight hours amounted to nine maunds and was three times greater. Nearly 30 per cent economy in fuel consumption can be effected by the adoption of the improved type of furnace. A mechanical appliance devised at this Station for polishing turmeric has also proved very useful.

(iii) Regulating quality of exports

There are frequent complaints in the foreign markets regarding the quality of turmeric exported from India. It is stated that the Indian product is weevil-infested and that it is often contaminated with the excreta of rodents, etc. Such complaints do great damage to the reputation of the Indian produce in addition to the financial loss caused to the exporters by way of reconditioning, cleaning, etc. at the destinations. It is, therefore, of importance to regulate the quality of exports by fixing suitable grades and grade specifications.

It is reported that considerable quantities of turmeric powder enter the internal trade. The produce available for internal consumption is, however, of uncertain quality and is often found adulterated with ingredients which are dangerous to health. There is, therefore, scope for developing the internal sale of quality turmeric powder in suitable containers.

4. SUMMARY OF CONCLUSIONS AND RECOMMENDATIONS

(i) General

Turmeric is a minor crop of the West Coast which has no special importance in the agricultural economy of the tract. During its study tour of these regions, the Spices Enquiry Committee did not, therefore, get adequate evidence concerning the problems of this industry. Nor has the committee visited the East Coast districts of Madras, the agency tracts of Orissa and certain parts of Bombay and Hyderabad which are the principal producing areas of this crop. The present report is, therefore, based on a rapid study tour of only some of the minor producing areas and on the limited information supplied by official agencies. Available information shows that although turmeric is a minor West Coast crop, this industry has sufficient importance in other parts of the country and in internal trade. A detailed marketing survey should, therefore, be conducted by the Central Government in order to assess all the problems concerning this industry. We are also convinced that the development of this industry should be separately planned and executed and should not be brought within the present scope of the central and regional advisory committees we have recommended for the other five commodities.

We are, however, giving below a few of the outstanding problems of this industry as have come to our notice and our recommendations thereon.

(ii) Need for all-India crop estimates

The average annual acreage under the turmeric in India has been estimated at 1,35,000 acres and the total out-turn of the crop has been reckoned at 1,20,000 tons expressed in terms of dry cured product. Excepting about 10,000 tons exported to the overseas markets, the rest of the crop is almost entirely utilised in India. Reliable statistics of production and internal consumption are not, however, available. Considering the importance of this product in internal trade we recommend that the Central Government should arrange to publish regularly all-India forecasts of area and yield of turmeric.

(iii) More research stations

Except in Orissa, no systematic attempt has been made to develop the industry on scientific lines. There is urgent need for improving the local varieties under cultivation and for finding out suitable remedies for seed diseases which are carried from season to season. Arrangements should therefore be made to start turmeric research stations in all other typical producing areas. These stations should tackle all the problems of botanical and agronomic improvements concerning this crop including problems of storage and control of stored products pests.

(iv) Credit facilities

Like ginger, turmeric is also an expensive crop to grow and requires financial assistance during the cultivation season. Greater production credit should therefore be made available to the cultivators through the co-operative agencies.

(v) Transport

In common with all other agricultural commodities, the marketing of this crop also suffers because of lack of suitable communications, particularly in the agency tracts of Orissa. Improvements in this direction are, therefore, necessary to open up the producing areas.

(vi) Better equipment for curing and polishing

The improved type of furnace evolved at Orissa has been found to be more efficient and economical in fuel consumption than the local type. The cured product when also polished by the equipment evolved in this State has fetched a premium of 20 per cent. Greater use of these and similar equipments should be encouraged by the agricultural departments of the States concerned.

(vii) Foreign publicity

The principal importers of Indian turmeric are Ceylon, South Africa, Iran, Aden and dependencies, the U.S.A. and U.K. Besides these many other countries also import turmeric from India though in small quantities. In all trade exhibitions organised by the Government of India in foreign countries, greater publicity should be given to this product in order to increase the off-take.

(viii) Uniformity in grade standards

Turmeric has well-defined quality factors which are also recognised by the trade. These factors should be taken advantage of for framing uniform grades and grade standards under the Agricultural Produce (Grading and Marking) Act.

A sizable proportion of the turmeric trade takes place in the form of powder. As there are serious complaints regarding its quality, grades and grade specifications for this product also should be framed and effort should be made to induce the trade to adopt these standards for internal distribution.

CHAPTER V

CASHEWNUT (KAJU)

1. GENERAL OUTLOOK

Although the cashew tree, (Anacardium occidentale), is met with in many tropical and sub-tropical parts of the world the seeds of the tree known as the cashewnuts are collected on a commercial scale only in India, East Africa and Brazil. The Brazilian crop is comparatively smaller and by far the largest quantities of cashewnut are produced in India and East Africa. The entire East African crop is, however, exported as raw nuts to India and the processing and manufacture of cashew kernels are almost entirely carried out in India. India is thus the principal source of supply of cashew kernels and bulk of the requirements of the world markets are also met from this source. Over 90 per cent of the world demand is estimated to be met with by the Indian industry and the small balance is contributed by other countries mostly Brazil.

With the growing demand for cashew kernels in the world markets, there is an increasing realisation of the commercial importance of this industry. The increasing popularity of this product may be noticed from the quantities consumed in various countries during the last quarter of a century. The increased consumption has been noticed particularly in the U.S.A. where the quantities annually consumed have increased from less than 50 tons in 1925 to as much as 20,000 tons at the present time. Consumption has similarly increased in Australia. South Africa and most of the European countries also. Efforts are, therefore, being made in some of the producing areas particularly in Africa to develop the cashewnut processing industry and to extract the kernels on a commercial scale.

In Africa, the cashewnut crop is distributed mostly in Portuguese East Africa and to some extent in the southern province of Tanganyka on the coastal belt and in the interior as far west as Masasi, Newala and Nachingwea. Based on the place from which they come, the African nuts are known as Mozambique, Angoche, Ibo and Lorenco from Portuguese East Africa and Angoche and Dares-Salam from British East Africa. Almost the entire exportable cashewnut crop from these regions goes at present to India for processing. But attempts are being made by some of the European firms experienced in India to set up factories in these producing areas. The only factory processing cashew kernels in East Africa is a small concern at Kailifi in Kenya. The authorities in Africa, are also encouraging the processing of local nuts and are trying to organise the industry in other ways. But the main difficulty in all these areas has been noticed to be inadequate supply of skilled and experienced labour. Most of the processing is done by manual labour and as they are not readily available at low rates of wages as in India, the manufacturing costs are high and these concerns are not able to compete with the Indian kernels. This position is not likely to be disturbed in the near future. India should not, however, rely too much on the supply of imported nuts to meet the needs of the factories and the export trade. The dependence on foreign nuts should be reduced to the minimum and necessary measures taken to step up indigenous production so as to reduce the costs and offer more competitive prices in the world markets.

2. Position of the industry in India

(i) Some facts regarding cultivation

The cashew tree (Anacardium occidentale) is not a native of India but has been introduced into this country from Brazil by the Portuguese nearly 400 years ago. Although first introduced for the purpose of checking soil erosion, the cultivation of this crop has gained great commercial importance in India during the last quarter of a century. The tree is grown for its fruits which are known as cashewnuts, The cashewnuts are processed further to obtain the oil and inner kernels which have great commercial value.

The cultivation of the cashew nut crop is concentrated in the West Coast and East Coast of the peninsular India. By far the largest area of this crop is found distributed in the Madras State in the two districts of Malabar and South Kanara. To a small extent the crop is grown in the East Coast in the districts of Vizagapattam, South Arcot, Tiruchirapally, Tanjore and the East Godavari. Cashewnut trees are also found scattered in several other districts of the State including Chinglepet and Guntur. In Travancore-Cochin, which is the next important growing-area for cashewnut, the tree is met with practically in all parts of the State but the talukas of Chirainkil, Kottarakara, Kunnauthnad, Trichur, Kilimanoor and Kunnamkulam are the most important. The crop is met with in parts of Ratnagiri and North Kanara districts of the Bombay State and also in portions of Mysore and Coorg.

Ordinarily the tree grows to a height of 20 to 25 ft. in plantations but under certain favourable conditions, reaches far greater heights. It has an extensive root system and is, therefore, able to establish itself even on poor and rocky soils as waste lands are generally selected for the cultivation of this crop. It grows on laterite soils with a rainfall of over 120 in. as in the West Coast and does equally well on the sandy soils of the East Coast districts of Madras where the rainfall is less than 35 in. It is drought-resistant but cannot withstand frost. The cultivation of this crop depends entirely on seasonal rains and a regular monsoon, therefore, becomes an essential condition for the successful cultivation of this crop.

At present, no systematic method is adopted for the cultivation of this crop. The tree is grown in gardens, and house-compounds inter-spersed with mangoes, coconuts and arecanuts. Invariably, it is planted in the corners of numerous house-compounds and outlying areas which are considered as unsuitable for the growing of any other crop. The cultivation is simple and does not consist of any elaborate preparatory or after-cultivation operations. When grown on a plantation scale, small pits are dug at a distance of 25 to 30 ft. at the beginning of the south-west monsoon and one or two dry cashewnut seeds (with shell) are put into each pit and covered over. The seed germinates rapidly within two weeks and develops an extensive root system. Thereafter, practically no

attention is paid to the crop either by way of watering, manuring or other kinds of inter-cultivation, and being a very hardy plant it comes up well even under diverse conditions of soil and climate. Flowering takes place in the months of December and January. Light showers at this time are said to be beneficial for the crop whereas prolonged cloudy weather at this stage is said to reduce the yield of nuts. The fruits which consist of swollen peduncles known as cashew apples and the cashewnut borne on the extreme end, are harvested in the months of March, April and May. The actual yield per tree depends upon a variety of conditions and may vary from about one pound of dry raw cashewnuts per tree in the case of close plantations to as much as 40 to 50 lb. per tree where only 60 to 70 trees are planted per acre. In Travancore-Cochin, number of trees planted per acre has been found to vary from 50 to 200 in Quilon and Kottarakara, and as much as over 1,000 in some of the areas in the Trichur district. In the latter case it was noticed that the crop was grown mainly for fuel purposes. In the forests of Mysore State where the cashewnut plantations have been recently introduced, the number of trees varies from 75 to 100 per acre which seems to be the optimum number to be planted on a plantation basis. On an average the yield per tree on the West Coast may be taken to be 20 lb. while in the eastern districts it is slightly higher. The higher yield on the East Coast is largely attributed to the scattered nature of the crop and its consequent greater growing areas.

The cashew tree generally begins to bear fruit three or four years after planting. Upto the tenth year the yield is poor but it goes on increasing and between the seventh and tenth year the maximum yields are obtained. Thereafter, for about 20 years the tree yields a satisfactory crop. The average life of the cashewnut plantation is estimated to be 35 to 40 years.

(ii) Total area under cultivation

The total area under cashewnut cultivation in 1951-52 was 2,23,128 acres distributed as follows:

Madras	1,35,039 acres
Travancore-Cochin	82 , 925 ,,
Bombay	4,509 ,,
Coorg	155 "
Mysore	500 ,,
	·
Total	2,23, 228 acres

Accurate statistics of this crop are not maintained in the producing States but available information shows that with the rapid development of the cashewnut processing industry the acreage under this crop has also greatly increased in recent years. The maximum increase has taken place in the Madras State where the crop has increased from about 45,000 acres during the pre-war period to 1,35,039 acres at the present time. We noticed that there is further scope for extending cultivation in Malabar and South Kanara in

the West Coast and in the East Coast districts of Chinglepet, Tanjore, East Godavari, South Arcot, Visakhapatanam and Tiruchirapally. Similarly, the crop could be extended in other growing areas also particularly in North Kanara and Ratnagiri districts of the Bombay State. The fact that the cashewnut tree comes up well even on waste lands in these areas should be taken advantage of to extend its cultivation. It is a cash crop which increases the small income of the common man and can be cultivated, without affecting the raising of food crops. With suitable encouragement, the area under this crop could be considerably increased in India.

(iii) Internal supply of cashewnuts

The indigenous production of raw cashewnuts during 1951-52 was estimated at 60,100 tons, as shown below:

Madras	33,000 tons
Travancore-Cochin	20,000 ,,
Bombay	4,500 ,,
Others	2,600 ,,
Total	60,100 tons

More than half of the total production of cashewnuts is in the Madras State concentrated mainly in the two West Coast districts of Malabar and South Kanara. These two districts together account for nearly two-thirds of the total production in the Madras State. Travancore-Cochin produces small quantities and it is the next important producer of raw nuts. The processing of raw nuts is also largely carried out in this State in its factories at Quilon. Nearly 150 factories are located at Quilon and more than three-fourth of the export trade in cashewnut kernels also emanates from this State. In the Bombay State, cashewnut production is confined mainly to the coastal districts of Ratnagiri and North Kanara of which the former is the more important. The areas of concentrated production in the Ratnagiri district are the talukas of Vengurla and Malwan which are also the important processing centres for this crop.

The crop produced in other areas is small and includes those obtained from Coorg and Mysore and certain areas of West Bengal and Orissa.

The total supply of cashewnuts in different States of the Indian Union during 1951-52 has been reckoned at slightly over 60,000 tons. As against this figure, the total supply during 1938-39 to 1940-41 has been estimated at 45,400 tons which shows that cashewnut production in India has increased to the extent of nearly 15,000 tons or 33 percent during the past decade. Both the area and production show an increasing trend in recent years and enquiries have shown that there is further scope for expanding the cashewnut cultivation in most of the producing areas so as to meet the needs of the Indian factories and our export trade.

Cashewnut is produced in very small holdings, each cultivator often owning not more than a few trees. The existing trees are found scattered and the outturn available for sale with an average

farmer is, therefore, too small, not exceeding a few pounds. The majority of these small producers do not find it worthwhile to take their produce to large assembling markets or factories.

A major portion of the crop is collected by itinerant dealers who during the marketing season go about from house to house in the main producing areas and collect their produce. A small quantity of the nuts is disposed of by the farmers themselves at the primary markets. At these primary markets, the itinerant merchants operate and collect the produce from producers. During the marketing season, a number of wholesale merchants and agents of various processing factories begin functioning in these primary markets and provide a keen competition for the purchase of these nuts. Through a broker they contact the itinerant merchants who have got adequate quantities of these nuts and arrange for purchases. itinerant merchants arrange to supply specific quantities and get immediate payment. Such business deals are made without even seeing the sample or examining the quality of the nuts. itinerant merchants and the brokers almost dictate the price but very little of this benefit is passed on to the producer. The margin of the itinerant merchants very often varies from 10-20 per cent of the value of the produce.

As already stated the processing centres in India are concentrated in the West Coast at Quilon. More than 150 factories are located in this place. A major portion of the Malabar crop and almost the entire supplies of Travancore-Cochin are purchased by the Quilon factories. Only a very small percentage of the crop is utilised at Calicut and at Mangalore for being processed into kernels. The buyers dry the nuts before despatch to the various processing concerns and make a deduction for the loss due to driage, while making payment to the producer.

(iv) Imports of raw nuts from foreign countries

Although India is the largest producer of cashewnuts, large quantities of raw nuts are also imported into this country. In 1951-52, the total imports of raw unshelled cashewnuts into India amounted to 42,353 tons valued at Rs. 3.27 crores. During the current year, the quantity and value of the imports have both increased and amounted to 51,682 tons and Rs. 4.66 crores respectively (vide appendix XXIX). The actual quantities imported vary from year to year and largely depend upon the indigenous production of raw nuts as well as the export demand for cashew kernels in the world markets.

It will be seen from appendix XXIX that the main source of our imports of raw cashewnuts is East Africa. Both British and Portuguese East Africa supply this raw material to our processing factories but by far the largest quantities are obtained from the latter territory. With the growing world demand for cashew kernels, there is increasing realisation of the commercial importance of this crop in East Africa, particularly in the British Zone where some plans are already afoot to set up processing factories and to utilise the local supplies. Due to the difficulties of labour and uncertainties in the political conditions, these plans have not as yet made much head-way; nor are they likely to progress rapidly in

view of the heavy costs of processing in those countries. Our supplies of raw nuts from this source are not likely to be cut off in the near future but the authorities should take note of these trends in the industry and make early arrangements for reducing India's dependence on these foreign imports by stepping-up indigenous production for which there are immense possibilities.

The imports and distribution of these African nuts are arranged by a few leading firms operating in Bombay. Having branches at the East African ports and established long business connections with these regions, these firms are very influential and hold almost a monopoly in the import trade and all the processing factories are obliged to obtain their requirements through them. The factory owners place their orders through these firms which then arrange to import the required quantities through their branches in East Africa. The cashewnut season in different parts of Africa being from November to March, the imports into India are also comparatively larger during this period. Purchases are arranged on forward celivery basis and necessary business transactions are settled in August-September before the cashewnut season commences in that country. Up to March, therefore, the Indian factories make use of the imported nuts and from March onwards utilise the indigenous crop which starts moving into the markets by then. Nearly threefourth of the imported quantities are purchased by the processing factories at Quilon in Travancore-Cochin and the rest largely by those at Calicut and Mangalore.

The imported nuts as well as the local crop are utilised for the manufacture of kernels but the total supplies are found to be inadequate to meet the requirements of the processing factories. Most of these factories find the present supplies sufficient only for 9 to 10 months in a year and have to remain idle for the remaining 2 to 3 months. This clearly emphasises the urgent need for expanding the local cultivation of this crop.

The main point in favour of the imported cashewnuts is that their loss of weight during drying or transit is very small. This is due to the fact that in East Africa, particularly in the southern Provinces, the nuts are not gathered till these have fallen to the ground from the trees. The produce collected is, therefore, fully ripe and mature and the kernels inside are also fully formed. In India, on the other hand, due to scarcity of supplies and demand from the factories large quantities of immature nuts are annually plucked from the trees and marketed in this State. The loss of weight of these nuts during drying has been found to vary from 10 to 15 per cent. This loss could be avoided and the indigenous supply of raw nuts could be increased if we could stop the practice of harvesting unripe nuts. In East Africa, the nuts begin to mature from September onwards but the crop is gathered only after it has fallen to the ground and the marketing season commences still later. Similar delays in the marketing season of the crop would be helpful to obtain larger proportion of mature nuts in the commercial supplies to the factories.

(v) Total supply of raw nuts and processed kernels

The total supply of raw unshelled cashewnuts in India during 1951-52 has been estimated at 1,02,353 tons which included 60,000

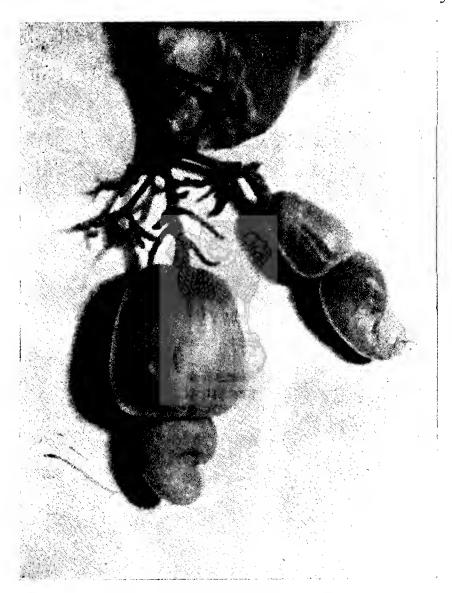

Fig. 26. Cashewnut attached to the swollen peducles or cashew apple

सन्त्रपंत्र नवने

tons of indigenous production and 42,353 tons of imported nuts. The average recovery of cashew kernels is estimated at 25 per cent in the case of Indian nuts and 26 per cent in the case of African nuts. On this basis, the total outturn of kernels of the various cashewnut processing factories in India may be reckoned at 26,000 tons. In 1952-53, the total supply increased by nearly 3,000 tons. In as a result of the processing of the larger quantities imported during the season.

(vi) Processing

The cashew kernels of commerce are obtained by processing the raw unshelled cashewnuts in various ways. These include such processes as roasting, shelling and peeling. Roasting makes the shell brittle and facilitates the extraction of kernels and also imparts a special flavour to the kernels. To obtain kernels of good quality, the raw nuts have to be uniformly roasted. Until recently, the main object of roasting was only to obtain uniform roasting, but with the increasing importance of cashew shell liquid, attempts are being made to evolve a process which combines uniform roasting with the maximum recovery of the shell-oil also.

Roasting is both a delicate and difficult process and unless it is properly done the quality and recovery of kernels are adversely affected. The pungent smoke which escapes during the roasting of nuts is injurious to health and the cashew shell liquid which exudes from the shells has a corrosive action on the hands and fingers of the workers. While some of the factories paid attention to these factors, the standard of amenities provided to the workers in others was found to be poor. Unless adequate facilities are provided to safeguard the health of the workers, majority of whom are women, the efficiency of the workers will not improve.

The four methods generally employed for roasting are (i) open pan, (ii) earthern-wares, (iii) rotary cylinders and (iv) oil baths. The first two methods are simple and are more widely adopted in all the producing areas. They are also cheap and do not involve any capital outlay. The main defects are that there is no proper arrangement for the recovery of the oil or to protect the worker against the fumes and oil escaping during the process. The rotary cylinders are an improvement over the open pans or the earthernware method of roasting cashewnuts. This system is also efficient and hygienic as far as roasting is concerned, but a larger proportion of the shell-oil is not recovered by this method also. The cost of setting up rotaries is, however, far higher as compared to the previous two methods. The new method combining good roasting with the maximum recovery of shell-oil is provided by the oil bath system. The oil-bath system, as its name implies, provides an oil bath consisting of cashew shell oil itself, the temperature of which is maintained at about 200°C. Raw cashewnuts which are to be roasted are held in wire trays and passed through this hot oil bath for about one minute during which time, due to the high temperature of the bath, the oil cells of the raw nuts burst and release the content into the oil bath. The overflowing oil is drained and collected simultaneously. At the same time, the shells get roasted to

the desired degree so as to facilitate the extraction of kernels. Although this system is most efficient, it is too costly to be widely adopted in the manufacturing centres.

After roasting, the shells have to be removed from the roasted nuts and the kernels have to be extracted. Unless the shelling is done carefully and skilfully, the kernels are likely to be broken and the recovery of whole kernels is bound to be poor. The shelling operations are, therefore, done by hand by employing a large-number of labourers, mostly women. The kernels as extracted from the shells are covered with a thin brownish skin or outer coating which has to be removed before the produce can be made fit for human consumption. To facilitate peeling, the kernels are first dried in the sun or in specially constructed hot-air chambers. Likeshelling, peeling is also carried out by human labour, consisting, mostly of women and children.

The kernels as received after peeling are in a dry and brittle condition and are liable to breakage during package and transport. These are, therefore, allowed to absorb some moisture by keeping in moist chambers before these are finally packed into tins for export purposes.

It was noticed that most of the processes involved in the manufacture of commercial cashew kernels were being done by manual labour. Apart from being an important producing area, the availability of sufficient skilled labour at low rates of wages has been largely responsible for the concentration of the cashewnut processing factories in the West Coast.

(vii) Number and location of processing factories

Up-to-date statistics of the actual number of cashewnut processing factories in India are not available. It is, however, estimated that these number in all over 140 out of which about 50 factories are registered under the Factories Act and the rest are all managed on a cottage industry basis and do not, therefore, maintain proper records of production.

Most of these processing factories are situated in Quilon in Travancore-Cochin. More than 100 of these are concentrated in this region and half of the remaining number is distributed in Malabar (Calicut) and South Kanara (Mangalore). The proximity to the producing areas and the availability of sufficient skilled and experienced labour at low rates of wages have largely been responsible for the concentration of these factories in these regions. Other factories are located in the East Coast districts of South Arcot (Panruti), Guntur (Vetapalam) and Visakhapatnam (Palasa) as well as at Malvan and Vengurla in the Ratnagiri district of the Bombay State.

(viii) Average recovery of kernels and shell oil

On an average, the weight of the cashewnut shell comprises of 70 to 72 per cent of the total weight of the raw cashewnuts. The weight of the unpeeled kernels thus amounts to 28 to 30 per cent of the unshelled nuts. Nearly 12 per cent of this represents the

Fig. 27. Percentage export of cashew kernels from India to different countries of the world

weight of the peels and only the remaining is obtained as the cashew kernel of commerce. The kernels are recovered as wholes brokens, and splits and the percentage recovery of different qualities has worked out as follows in one of the factories:

Whole kernels—best quality	9.94 per cen
Second '	5.69 ,,
Brokens—best quality	4.10 ,,
Second	5.33 "
Total	25.06 per cent

The best wholes consist of 210 to 400 counts. But the yield of higher counts such as 210 and 240 is negligible in the case of the inferior imported nuts which gives more of 280 s. and 320 s. only. The Indian nuts are, therefore, preferred for obtaining high grade kernels.

The Indian nuts are preferred also for the extraction of the cashew-shell liquid. The shell comprises of 70 to 72 per cent of the total weight of the raw nuts and 24 to 25 per cent of the weight of the shell consists of the oil known as cashew-shell liquid in commerce. Actual recovery of oil in most of the factories is, however, much smaller and averages only 10 to 12 per cent even by the oilbath method of processing which emphasises the need for further improvements in the methods of processing.

(ix) Export trade in kernels

Bulk of the cashew kernels processed in India are exported to the foreign markets. With the modern developments in packing, the pace of these exports has also quickened in recent years. The export of cashew kernels from India was hardly less than 1,000 tons nearly a quarter of a century ago. This increased to 14,000 tons before the war and reached the maximum of 27,417 tons during 1952-53. The value of these exports has also correspondingly increased from Rs. 1·29 crores before the war to Rs. 12·76 crores during the current year. More than three-fourth of these quantities are exported to the U.S.A. which is our largest consumer. Other important importers are the U.K. and Canada but their off-take is comparatively small (vide appendix XXX and diagram). Considering the growing popularity of the Indian cashew kernels in these consuming markets, there is further scope for expanding our world trade in this commodity and for earning more foreign exchange.

The cashew kernels exported to the various countries are of recognised quality. Generally bold and whole kernels are in demand for export purposes but considerable quantities of brokens are also exported from India. Apart from these wholes and brokens, a third quality known as 'scorched' is also exported. The scorched kernels

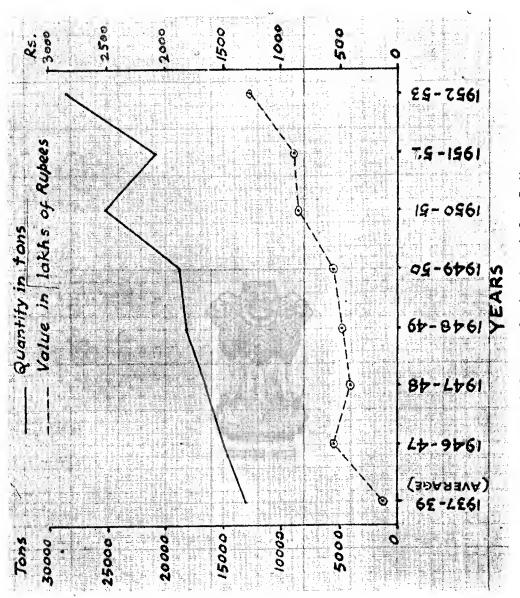

Fig. 28, The trend of export of cashew kernels from India

सन्त्रपंत्र नवने

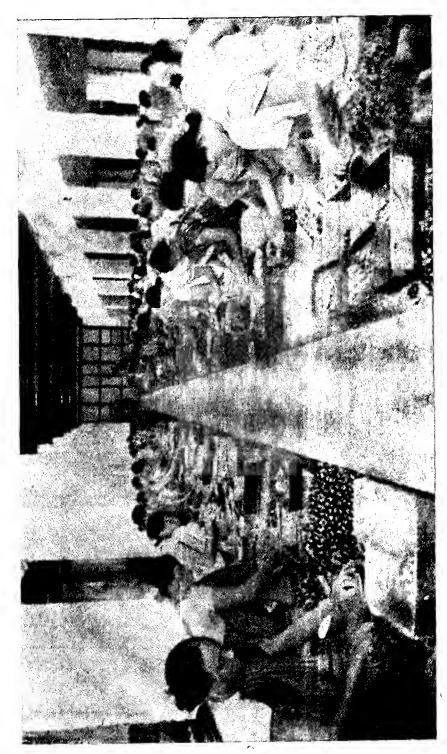

Fig. 29. Shelling of cashewnuts in one of the factories in the West Coast.

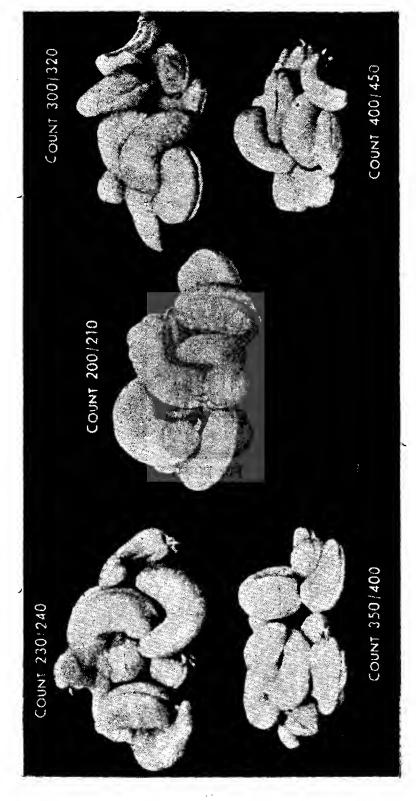

Fig. 33. Different grades of whole kernels based on 'Counts' (American standard)

represent the over-roasted kernels which have a little burnt appearance. Second sorts of these three main qualities are also widely prevalent in the export trade and are sold under the name of 'second wholes', 'second brokens', etc. Although the grades and qualities vary from firm to firm, the exporting firms are all aware of the specific quality characteristics based on the size, colour of the kernels and the proportion of brokens in the lot. The standards generally adopted are based on the 'count' system (American standard) which represent the number of kernels per pound of the lot. Although there are slight variations, the present system of grading and trade classification appears to be working fairly satisfactorily.

For export, the kernels are packed in standardised wooden cases containing two tins of 25 lb. each. After filling the tins with the kernels, the tins are hermetically sealed usually by the vita-pakemethod. Certain firms pack the kernels under carbon dioxide gas which is introduced into the tins after exhaustion. The storage life of cashew kernels under these conditions exceeds one year. In spite of these precautions, foreign buyers sometimes complain of worminess in Indian consignments. The exporters should, therefore, remedy this defect by paying more attention particularly to (1) the environmental hygiene of the processing factories in India, (2) the use of new and better tin containers for packing kernels, (3) the wider use of airtight packing as in the vita-pak method and (4) by adopting uniform grade standards on an all-India basis.

(x) Internal trade in kernels

No reliable data is available to indicate the demand or trend of the internal trade. But the general view is that there has been a steady increase in the demand for this product in the home market. The demand and consumption of the roasted and salted cashew kernels has particularly increased. Due to their comparatively high prices, the consumption of these kernels is, however, as yet confined to the well-to-do classes in cities and towns. The total internal consumption is limited to hardly 2,000 to 3,000 tons. The main source of supplies are the East and West Coast regions. The production from the West Coast factories is distributed mainly through the Bombay port to other States of Northern India, particularly, Delhi, Punjab, Rajasthan and Madhya Pradesh. The kernels produced in the East Coast districts are despatched to Orissa, Bengal, Assam, Bihar and Uttar Pradesh.

Cashew kernels are used in India for a variety of purposes. The roasted kernels are consumed as such like other dry fruits or they are used for flavouring sweet dishes. There is also a growing demand for salted kernels in recent years. These kernels compare favourably with other dry fruits like almonds, walnuts and pistachios in food values (vide appendix XXXI) and their consumption is bound to grow provided the prices are within the means of the average consumer.

(xi) Prices

The trend of prices of both raw cashewnuts and processed cashew kernels may be seen from Table I.

TABLE I

Trend of oashewnut and kernel prices at Cochin

Yearly	Raw cashewnut (Rs. per md.)	Kernel (U. S. cents per lb., r—320 counts)
1942	6— 8	187
1943	9—ī1	267
1944	11-4	448
1945	14— o	384
1946	15—10	352
1947	. 10 9	240
1948	1 2 —13	261
1949	15 0	251
1950	18— 5	251
1951	20— 8	277
1952	26—12	_

The prices of both raw cashewnuts and the processed kernels have steadily increased since world war II (vide appendices XXXII to XXXIV). The increase has been, however, most marked in the case of raw nuts than in the kernels. From hardly Rs. 6-8 per maund in 1942, the prices of raw nuts increased by 215 per cent and stood at Rs. 20-8 per maund in 1951. While the kernel prices moved up from 187 cents per pound in 1942 to 277 cents per pound in 1951 and increased by only 48 per cent during this period. Compared with the general rise in the level of post-war prices, the increase in both these cases should be considered meagre. The comparatively larger increase in cashewnut prices is mainly due to the shortage of supplies and the greater demand from the various processing factories. With the improvement in the supply position of nuts, the processing factories will be able to reduce the production costs and be in a better position to offer more competitive prices for kernels in the consuming markets.

Price differences on account of quality also exist both in regard to the raw nuts and the kernels. The local nuts are superior and fetch a higher premium of generally 5 to 10 per cent over the imported produce. Even in indigenous production, certain localities are noted for their fully ripe and mature crop which, therefore, receives a premium of 5 to 6 per cent over the average qualities. In the case of kernels, the shipment qualities number over ten but

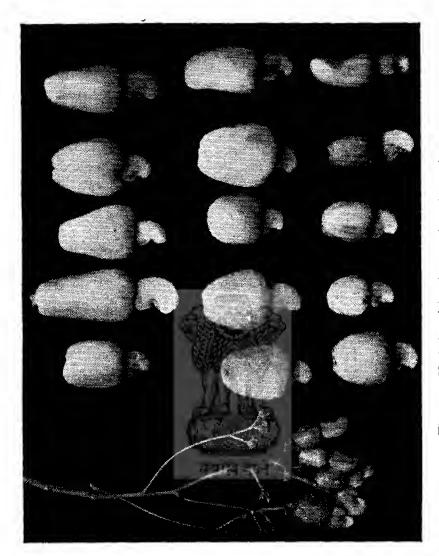

Fig. 31. Variations in cashew apple and nut characters

सन्त्रपंत्र नवने

these can be broadly classified under three qualities, namely wholes, bulbs and splits and pieces. The whole kernels are the best quality and are always in greater demand and these qualities receive 10 per cent higher price than that for the bulbs and splits and as much as 25 to 30 per cent more than that for the pieces.

(xii) Distribution of kernels

The main distributing markets for cashew kernels in India are Bombay, Calcutta, Kanpur, Delhi, Indore, Nagpur, Ahmedabad, Belgaum, Hyderabad and Bangalore. Wholesale merchants who deal in other dry fruits, spices and other articles in these markets contact the processing firms in the West Coast region as well as in the East Coast region and generally obtain their requirements direct from them. Prices are quoted on f.o.b. basis and the importers in these distributing markets have, therefore, to pay only freight and other incidental charges such as cartage, octroi and labour at their end.

The important centres of supply are Quilon and Alleppey in Travancore-Cochin, Calicut, Managalore and Panruti in Madras, Vetapalam and Palasa in the Andhra State and Malvan and Vengurla in the Bombay State. The kernels processed in the West Coast factories are mostly exported to the foreign markets. But the remaining quantities are distributed mainly through Bombay. Almost the entire output of the East Coast factories at Palasa, Vetapalam and Panruti is also utilised for inland distribution.

The distribution of the processed cashew kernels in the foreign markets is carried out chiefly by the factory owners themselves. Some of the large processing concerns have their own trade representatives or commission agents in New York while a few others combine themselves into a corporation and arrange for the distribution through a common office in the foreign markets. Other manufacturing concerns who have no such direct connection with the foreign markets sell their product to the former two agencies or to the commission agents at Bombay who also handle a small part of the export trade in cashew kernels. The representatives of these agencies in the foreign markets keep their parties in India informed of the position regarding stocks, trend of demand and prices and also arrange to secure orders for them from the buyers and are paid $1\frac{1}{2}$ to $2\frac{1}{2}$ per cent of the value of the sales effected through them as trade brokerage.

The distribution in the foreign markets is done in two instalments during the year, but is largely concentrated from September to December. The prices quoted during this period are on the basis of the quotations for the nuts imported from East Africa while the subsequent quotations which are made from January to March are on the basis of the prospects of the indigenous supply of cashewnuts. The exports are made on c.i.f. basis and on the basis of written contracts; and shipments take place within three or four months of the date of the contract. Ninety-five per cent of the invoice value is reimbursed on shipment of the consignment while the remaining five per cent is reserved by the foreign buyers against possible claims of quality. It has been noticed that the processing costs have remained stationary round about Rs. 5 per maund during the past few years. The charges for packing and transport have

also not increased. While the manufacturing costs have remained more or less constant, the freight charges have increased greatly. Before the war, the freight rates for shipment from Cochin to New York amounted to Rs. 55 per shipping tons of 28.25 cases containing 50 lb. each. This has increased to over Rs. 150 at the present time. Unlike the trade in raw cashewnuts, the distribution of kernels both in the inland and foreign markets is better organised and is conducted more efficiently. The main handicap noticed in most cases was in regard to publicity. With proper arrangements for publicity and contact in the foreign markets, various processing concerns could considerably increase their sales in these markets.

3. RESEARCH, TECHNOLOGY AND DEVELOPMENT

(i) Research

The Indian Council of Agricultural Research sanctioned three schemes of research on cashewnuts to be worked for five years with effect from the 1st April, 1951 in the producing areas of Madras, Travancore-Cochin and Bombay. According to these schemes, three cashewnut research stations will be opened at Mangalore, Kottarakara and Ratnagiri respectively in the above States. The main object of the Madras scheme is to extend the cultivation and improve the yield of cashewnuts from the existing plantations. The items of research to be covered under this scheme are (i) survey of the existing cashewnut plantations in South India, classification of different types and formulating a key for their description, (ii) selection of promising types including foreign varieties, (iii) standardisation of propagation methods, (iv) raising and trials of promising types, (v) study of the factors influencing flowering, bearing and fruit setting and (vi) the study of the relationship between soil and the nutrients and soil-moisture on flowering and fruit setting.

The research work at the Bombay and Travancore-Cochin stations will be confined to the study and applications of the cultural practices and will include such specific items as (i) regional survey with a view to selecting suitable varieties for perpetuation, (ii) evolving suitable nursery techniques of the region, (iii) testing of selected varieties and (iv) the study of factors influencing flowering and fruit-setting.

Although the schemes are quite comprehensive, the stations have not started active research work mainly due to lack of financial assistance from the respective State Governments. Being busy with their food production activities, it is not likely that these States will also be in a position to divert funds for the development of this industry. The question of full central assistance for a specified period should, therefore, be explored. Being a perennial crop, permanent results can be expected only by working the schemes for a period of 10 years.

These research stations should also carry out investigations on the local pests and diseases of the crop. There are not many pests or diseases noticed on this crop but it has been reported that the 'die-back' disease causes serious damage in some years to the cashewnut plantations in South Kanara and Malabar while the stem-borers form the major source of trouble in other areas. Effective plant protection measures against these diseases and pests should be found out.

(ii) Technology

Until recently, extraction of kernels with minimum breakage losses has been the main objective aimed at in the cashewnut industry. With the increasing realisation of the technological possibilities of the cashew-shell oil, the extraction of oil has also assumed great commercial importance. Statistics of the total supply of oil or of the quantities exported are not available but it is estimated that the annual production of cashew-shell oil in the various factories of India varies from 7,000 to 9,000 tons and the total value of the exports made in 40—45 gallon drums exceeds over Rs. 60 lakhs. In 1942-43, the price of this oil amounted to hardly Rs. 120 per ton This has increased to over Rs. 1,200 at the present time.

Cashew-shell oil is a dark brown viscous liquid which has many industrial uses. These industrial uses are based on the fact that the oil polymerises to a rubber-like material under the influence of acids and also forms a wide range of condensation products with aldehydes. Though not a glyceride, it is a drying oil and is also easily soluble in most organic solvents.

The oil is directly used as a water-proofing agent and as a preservative in the painting of boats, fishing nets and light wood work. Besides these direct uses, it serves as an important raw material in many industries such as the manufacture of insulating varnishes, type-writer, rolls, oil and acid-proof cold-setting cements industrial flooring tiles and automobile brake linings. It is also used in the preparation of cement and adhesive ingredients, pigments for gums, inks, oil-cloth, paints, varnishes, etc., and water-proofing paper and card-board-finishing reagents. Considerable research has been conducted both in India and foreign countries on the technological possibilties of this oil. What is required is to give wider publicity to these findings among the Indian industrialists. Researches should, however, be carried out for finding out some uses for the cashewnut shells and also for evolving a cheaper type of oil-bath machine for the extraction of the oil.

Chemically, the cashew-shell oil consists of anacardic acid cardof and fatty matters and has been found to have the following analysis:—

Specific gravity at 26°C	1.0131
Refractive index at 41.5°C	1.5158
Saponifications number	119
Iodine number	296
Acid number	1.07

As the industrial utilisation of this oil will depend largely upon the quality of the product, it is necessary to manufacture standard qualities. The Indian Standards Institution has already framed some standard specification in this connection. Attempts should now be made to encourage their adoption by the various manufacturers.

Another by-product of the cashewnut industry which offers scope for technological research and development is the cashew-apple. These are the swollen peduncles supporting the cashewnuts. When ripe, these apples are quite sweet and being rich in sugars, the 128 I. C. of A. R.

juice can be boiled into syrups. It can also be used for making vinegar, jams and fruit preserves. Nearly 2,70,000 tons of cashew apples are estimated to be produced in the country annually but only less than 15 per cent are at present utilised for various purposes. There is, therefore, scope for greater utilisation of this byproduct which should be fully exploited.

(iii) Maintenance of statistics

Statistics are not maintained in India in regard to the area under cashewnut cultivation or of the production of nuts and processed kernels. Nor is any information readily available regarding stocks and internal trade movements. Such information is particularly needed in the case of the cashewnut industry where most of the factories are reported to remain idle for nearly 2 to 3 months of the year. The planning and development of the industry will be greatly facilitated if such data are regularly maintained.

(iv) Publicity in foreign markets

Specific instances have been brought to our notice that the cashew kernels from India are sometimes sold as of Brazilian origin in the American and other foreign markets. Early measures should be taken by the Central Government to counteract such fraud in respect of the origin and quality of the Indian product by making proper arrangements for publicity in the foreign countries. These measures should include also the preparation of a documentary film and its exhibition in all consuming markets.

Publicity should also be given regarding the rich food values of the cashew kernels. Experiments have shown that the cashew kernels of commerce compare favourably with such other dry fruits as walnuts or almonds as regards their oil, protein and vitamin contents. There is already a growing demand for this product and with dissemination of such information, the demand for this dry fruit is bound to increase both in the internal and foreign markets.

4. SUMMARY OF CONCLUSIONS AND RECOMMENDATIONS

(i) General outlook

Though Africa and other tropical countries are important producers of raw cashewnuts, the processing industry is concentrated in India. India forms the principal source of supply of cashew kernels in the world markets and accounts for more than 95 per cent of the international trade in this product. With the growing demand for cashew kernels in America and Europe, this Indian industry has a bright future.

(ii) Main problem

Out of 26,012 tons of cashew kernels produced in India during 1951-52, nearly 21,000 tons were exported and entered into international trade. Nearly half of this quantity was extracted from raw cashewnuts imported from East Africa. These imports from foreign countries are valued at Rs. 3.3 crores. The immediate problem of the cashewnut processing industry is to reduce India's dependence on foreign imports by taking early steps to increase the supplies of raw cashewnuts within the country.

12.

In spite of the large quantities imported into the country, the cashewnut processing factories in India did not have adequate supplies of raw cashewnuts to utilise their present installed capacities to the full. It was found that both the local production and the imported nuts provide work only for 9 to 10 months of the year and for the remaining period, the factories have to remain idle. This clearly emphasises the urgent need for stepping up internal production of cashewnuts in any case.

(iii) Increase internal supply of raw cashewnuts

In India, the cultivation of the cashewnut crop is concentrated in the western sea-board. There are, however, extensive lands available for cashew cultivation in the East Coast region of Madras, the coastal districts of Ratnagiri and North Kanara in the Bombay State and parts of Coorg and Mysore. In all these regions, extensive cultivation of the crop on a plantation basis should be encouraged. The forest departments in the producing States should also encourage its spread and growth in all the reserve areas and arrange to collect the nuts along with other minor forest produce. Wherever possible, the Public Works Departments should also undertake to extend the cultivation of this crop in suitable lands under their jurisdiction. A Coordinated Ten Year Plan (Cashewnut Plantation Scheme) should be prepared in this connection in consultation with the State Governments and put through expeditiously.

(iv) Greater central aid for agricultural research

Although sanction has been accorded by the Indian Council of Agricultural Research for the starting of three regional research stations for cashewnut at Madras (Mangalore), Bombay (Ratnagiri), and Travancore-Cochin (Kottarakara), actual research work has not commenced in any of these regions, mainly due to the lack of funds. We recommend that adequate funds should be made available by the Central Government, so as to enable the respective States to overcome the financial difficulties and start systematic scientific studies at these three research stations without any further delay.

The economic and botanical characters of the crop have received little attention at the hands of scientific workers nor has any effective remedy been found out for combating the pests and diseases of the crop such as stem-borer, powdery mildew, die-back, etc. All these aspects should be investigated at these research stations.

Although the cashew tree is propagated by means of seeds, vegetative methods have yielded promising results in some of the experiments conducted by the Madras Government. The potentialities of this method for the distribution of improved planting material should also be investigated.

(v) All-India crop estimates

Except what is given out by some of the leading business firms in the West Coast region, no attempt has been made by the Governments at the Centre or in the States to publish regular forecasts of the local production of cashewnuts, cashew kernels and cashew

shell liquid. Considering the size and value of the crop and the importance of the products as dollar-earners, it is necessary to maintain these statistics on an all-India basis.

(vi) Quicker transport to the factories

The movement of raw cashewnuts from the assembling centres or the ports to the factories has to be done quickly. Apart from pilferage losses, delay in this matter results in exposure of nuts to unfavourable weather conditions which adversely affect the recovery of good quality kernels. The railway authorities should, therefore, give greater facilities for the quick transport of the raw nuts to the processing factories.

(vii) Government assistance for procurement of raw nuts

While bulk of the Indian cashewnut crop is collected by itinerant merchants, the imports of foreign nuts are done mainly through a few influential firms for whom this forms only a side-business. The Government should, therefore, give all assistance to the factory owners in regard to the procurement of raw nuts from foreign countries.

(viii) Standardising local methods of marketing

The system adopted in the marketing of local raw nuts is defective in many respects. The various market practices and charges do not enable the producers in the villages to realise the maximum share of the price paid by the factory owners. The producer's share is sometimes reduced to as much as 50 per cent of the factory price. Even when the product is dry, deductions on account of driage are often made to the extent of 3 to 5 per cent. These market practices and charges prevailing in the village transactions should be put on a rational basis. As formation of producers' cooperative societies is difficult in the case of cashewnuts, we suggest that the buyers in the primary and assembling markets should be licensed by the State Governments and the Issue of such licenses should be subject to the condition that the licensee should buy only ripe and mature nuts and use standard weights in the transactions.

(ix) Adopting better methods of processing

Out of the various methods of processing employed in the extraction of cashew kernels from raw nuts, the oil-bath method is more efficient. By this method, the yield and quality of the kernels are better. The recovery of cashew shell liquid, which is a valuable by-product of the industry, is also greater in this case. The cost of the equipment and installation charges are, however, heavy. Small owners of cashewnut factories should, therefore, combine themselves into recognised associations and necessary financial assistance should be given by the governments to such associations in the form of loans for the setting up of such improved processing plants.

The Council of Scientific and Industrial Research should also take up for investigation the possibilities of evolving cheaper processing plants.

(x) Uniformity in grade standards

Excepting small quantities consumed in India the bulk of the cashew kernels produced in the country is exported to the foreign markets. These exports are according to the American standards of quality which are based on the 'count system'. Although this system is working satisfactorily, we consider that it will be helpful to the manufacturers and consumers alike if all-India standards of quality are framed for this product under the Agricultural Produce (Grading and Marking) Act and all price quotations are made on the basis of such standard qualities. These standards of quality should then be included in the trade contract terms also.

(xi) Regulation of quality

The main complaint heard about the quality of cashew kernels exported from India is that the product gets wormy in certain cases by the time it reaches its destination. The exports are made in standard wooden cases containing two tins of 25 lb. kernels in each. A number of cases shipped from India are reported to have been rejected on account of this defect. In order to minimise such complaints and maintain the reputation of Indian shipments, it is necessary to arrange for the regular inspection of these cases at the ports on a sample-test basis. In order to prevent development of worms in the cases shipped from India, factory owners should (1) pay greater attention to the environmental hygiene of the factory premises, (2) use new tin containers for packing kernels and (3) adopt air-tight packing.

(xii) Cashewnut Development Fund

At present, the cashewnut processing industry is concentrated in India and bulk of the world's requirements of these kernels is supplied by this country. The value of foreign trade amounts to Rs. 8-9 crores annually which can be increased further with further expansion of the industry. The exports being mostly to the U.S.A., the expansion of trade in this article will also improve the dollar position of this country. The Central Government should, therefore, create a separate fund and earmark a lump sum of Rs. 25 lakhs for undertaking the various developmental measures stated above. The administration and control of this fund should also vest in the central committee which we have already proposed for developing the spice industry in India.

(xiii) Indigenous utilisation of cashew-shell liquid

Nearly 7,000 to 9,000 tons of cashew-shell liquid are obtained every year as a by-product of the Indian cashew industry. This oil has many industrial uses and is, therefore, of great commercial importance. The oil is directly used as a preservative in the painting of boats, fishing-nets, light wood work and as a water-proofing agent. Its distillation products can be used in various industries such as the manufacture of insulating varnishes, typewriter rolls, oil and acid-proof cold-setting cements, industrial flooring tiles and automobile break-linings. Wider publicity should be given to these uses in order to encourage greater utilisation of this by-product by the indigenous industries.

(xiv) Standardising quality of cashew-shell liquid

All industrial uses of cashew-shell liquid presuppose a uniform quality of the commercial product. The Indian Standards Institution has drafted some tentative specifications for this oil, which should be adopted by the manufacturers to put a uniform product on the market. By such standardisation of quality, the exports of this oil to foreign countries are also likely to increase.

(xv) Publicity and sales promotion

It has been reported that the publicity for cashew kernels in the consuming countries is very inadequate. Specific instances have been noticed where even the origin of the product has been misrepresented. The special export-promotion agencies we have proposed in the case of pepper should undertake publicity work in respect of this product also in their respective areas.

Internally also, publicity is necessary to increase the demand for cashew kernels. Cashew kernels are already becoming popular in the Upper India markets particularly in hotels and restaurants and with greater publicity there are still further possibilities of increasing the demand for this product as an alternative dry fruit which compare favourably with almond, pistachio, etc.

(xvi) Amenities for the factory workers

Quite a large number of persons are employed by the Indian cashewnut industry. Although certain amenities such as fans, light, drinking water, nursery, etc. have been provided under the Factories Act, these were not found to be uniform or quite satisfactory in all the factories. Considering the difficult conditions and the nature of the work involved in processing, it is imperative that the standard of amenities provided in all these factories should be uniformly high.

CHAPTER VI LEMON-GRASS OIL (PUL THYLAM*)

1. General outlook

Oil of lemon-grass, which is a valuable dollar-earning article of India in recent years, is distilled from the leaves of the grass, Cymbopogon flexuosus, Stapf. Although the grass is met with in many tropical countries such as Ceylon, Java, West Indies and Malaya Peninsula, the systematic cultivation of this crop for distillation purposes is largely confined to India and Guatemala. Actual figures of production are not available but it is estimated that in 1951-52, the total supply of this oil amounted to 1000 tons, nearly one-fourth of which was accounted for by Guatemala and the remaining three-fourth by India. India was thus the largest producer and each year this country also supplied bulk of the world's requirements of this oil.

Lemon-grass oil is a basic raw material for the manufacture of many aromatic chemicals which find wide application in the perfumery, soap and cosmetic industries. The modern perfumers use this oil for the preparation of what are known as ionones. During world war II, large quantities of this oil were also used by the manufacturers in America and Europe in the synthesis of vitamin A. Besides these, the oil is directly used in many pharmaceutical preparations such as pain-balms and disinfectants.

On account of these industrial uses, the post-war demand and prices of this oil in the world markets increased considerably. Since last year, however, there has been a decline in the markets and the prices have also fallen. This is attributed partly to the larger supplies available in Guatemala and partly to the curtailment of demand particularly from the vitamin manufacturers in America and Europe. Unless steps are taken to stimulate the internal demand for this product for various industrial purposes, the prospects of the industry are not very bright.

2. Position of the industry in India

(i) Some facts regarding cultivation

Lemon-grass growing areas. Though lemon-grass is met with in the wild state in many of the slopes of the western ghats, the important growing-areas are in Travancore-Cochin particularly in the northern talukas of the State such as Kuruppampadi, Otakkali, Kothamangalam, Thodupuzha, Muvattupuzha, Vazhakulam, etc. The total area in the State during 1951-52 has been estimated at 35,000 acres.

With the migration of many of the enterprising cultivators from this State to the adjoining areas of Malabar, both the cultivation of this grass and the distillation of oil have extended to this region also, though on a much smaller scale. In the Malabar district, the area under the grass during 1951-52, has been reckoned at 4500 acres distributed mainly in the northern portions of the district such as Calicut, Wynad and Taliparamba. The total annual cultivated area under the crop is thus estimated at nearly 40,000 acres.

^{*} Malayalam name for the oil.

The grass grows with monsoon rains and is usually grown on hill slopes in hard laterite soils. Even the fertile slopes of the western ghats are said to be suitable for the raising of this grass so that the extension of cultivation of this crop does not present any difficulty.

Cultivation. The methods adopted for the cultivation of lemongrass are very simple and do not involve much expenditure. During February-March, the site selected for the cultivation of lemon-grass is cleared of all under-growth of vegetation by burning them. In April-May, when summer showers are received, two or three ploughings are given and the land is prepared into long narrow beds for sowing the seeds. About 15 to 20 lb. of seeds are used for sowing an acre. The seeds are sown broadcast and lightly covered by a brush harrow. Germination is generally complete in about 15 days. One month thereafter a combined operation of weeding, thinning and filling up the gaps is carried out in the field. No further care or aftercultivation is given to this crop except that occasionally during summer the stumps of large trees are burnt and the wood ashes spread in the field with a view to rejuvenate the crop. The crop is raised also by transplanting the seedlings raised in separate nurseries.

There are two varieties of lemon-grass found in the growing-areas. The one used for distillation purposes is the red-stemmed variety which gives better quality of oil containing as much as 85 per cent of citral. The second variety, which is characterised by its white stem and midrib, yields an inferior quality of oil with much lower citral content. Great care has therefore to be exercised in selecting the seeds only from these red-stemmed plant for planting purposes. Harvesting of the grass is done before the crop begins to flower, as otherwise the yield of oil will be poor. The grass is cut almost close to the ground. The first cutting is made four or five months after sowing the seeds but subsequent cuttings can be had at intervals of 40-45 days, and normally between July and December, five cuttings are annually taken for distillation purposes. During the hot and summer months prevailing thereafter no cuttings are possible from the crop.

The life of the crop varies from 5 to 8 years in each field depending upon its fertility and seasonal rainfall. The yield of grass is less in the first year of planting but during the second and third years the maximum yield is obtained which declines thereafter until the sixth year after which period the crop becomes uneconomical unless special attention is paid to it. On an average, however, the plantation lasts in the field for about six years.

(ii) Number and location of oil-distilling plants

The total number of stills which are at present engaged in the extraction of lemon-grass oil is estimated at 2,200. Nearly 2,000 of these are distributed in Travancore-Cochin and are concentrated around Kuruppampadi in Perumbavur taluka which is the main processing centre for this oil. The rest of the stills are located in the Malabar district in certain portions of Calicut, Wynad, and Taliparamba.

The stills in use are mostly of the indigenous type which vary in capacity from 8 to 18 cubic feet. The average type of country still takes about 200 lb. of green grass at a time, and completes the distillation in about $2\frac{1}{2}$ to 3 hours. During the busy season, 3 to 4 distillations are made in a still each day. Each of the present type of still

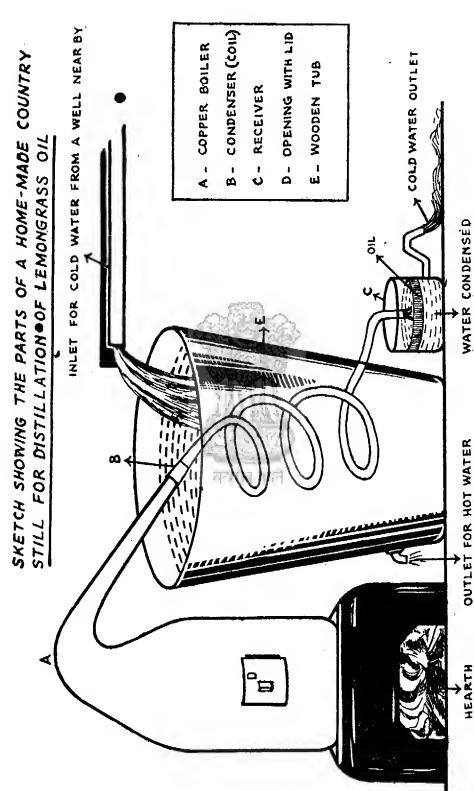

Fig. 32. Home-made country still for distillation of lemon-grass oil

of 80—90 gallons capacity costs Rs. 400 to Rs. 500 including the installation charges.

(iii) Mechanism of distillation

The ordinary country still used for the distillation of lemon-grass in India consists of three parts, viz. (1) the copper boiler-A, (2) the condenser-B and (3) the receiver-C as shown in the sketch. All these three parts are made of copper and are of local manufacture. The boiler (A) which is shaped like a retort tapering at the end is mounted on a raised hearth made of bricks or mud. Through the opening (D) on the body of the boiler, bundles of lemon-grass and water are admitted and the hole closed with a tight lid having a handle for letting in and taking out the charges. The boiler is generally made of thick copper sheets.

The condensing system (B) consists of a single copper spiral and is kept immersed in a cylindrical wooden tub (E) containing water. At the top, it is connected to the tapering end of the boiler while the bottom end projects into the receiver (C). The wooden tub in which the condenser is immersed has an open mouth through which cold water lifted from a neighbouring well is let in. It has also an opening at the side above the bottom for drawing off water as it becomes hot during the distillation process.

The receiver (C) is a small copper vessel which is fixed in the ground close to the condenser (B). The distillate collects in it in two layers, the upper layer consisting of oil and the lower layer consisting of water. On one side of the receiver just above the bottom, there is a bent tube which allows only water to flow out in small quantities leaving the oil at the bottom of the receiver.

Before starting the actual distillation, the inner sides of the boiler are cleaned. Thereafter, 300 to 450 small bundles of freshly cut lemon-grass weighing about 180-200 lb. and adequate quantity of cold water are introduced into the boiler through the opening. After introducing the charge, the lid of the boiler at (D) is placed in position and the joints plastered with cowdung and mud to prevent leakage. The hearth is then lighted by means of firewood and direct heat is applied to the boiler. As the heating proceeds, the greengrass boils in water and a mixture of water vapour and essential oil escapes through the tapering end into the condenser. As cold water is poured into the tube (E) at frequent intervals the vapours get cooled during their passage and collect inside the receiver in two separate layers, from which the water layer separates out through the outlet and oil layer remains at the top. The oil is collected and stored in bottles of capacities varying from 24 to 28 oz. For export purposes, however, 40-45 gallon steel drums are used. The time taken for completing one distillation is 21 to 3 hours and the firewood required for the purpose amounts to one hundred weight. Three to four distillation are generally completed in a day during the busy season.

Apart from the crude design and construction of the present equipment, a lot of firewood is consumed in the process. As extraction is done on open fire, it is not possible to regulate the temperature and considerable loss of oil also occurs by evaporation. This is further

aggravated by the fact that in the present equipment, there is no proper arrangement for cooling in the condenser. Nor is the arrangement satisfactory in regard to the separation of the oil from water in the final distillate. The problem of this industry is, therefore, to improve the present type of country still and evolve a more suitable type for the extraction of oil in these areas at cheaper cost.

In evolving a better type of distillation plant, the following defects of the present equipment will have to be remedied:

- (a) Wastage of fuel due to external heating
- (b) Incomplete recovery of oil
- (c) Deterioration in the quality of oil due to unregulated heating
- (d) Improper cooling system causing wastage of oil due to over-heating
- (e) Longer time for each distillation causing lower output
- (f) Inefficient receiving system
- (g) Formation of 'boiler-scales' inside the boiler causing its damage

Some suggestions for improvement are:

- (a) Under laboratory conditions, 20 per cent increase in the yield of oil has been obtained by adopting steam distillation. The citral content of the oil obtained by steam distillation was also found to be appreciably higher. Instead of direct heating, steam distillation should be preferred.
- (b) At present there is no proper arrangement for circulation of cold water with the result that there is no full recovery of oil. Continuous flow of cold water can be assured by fitting up an overhead tank.
- (c) From the distillate collected in the receiver the water (the mother liquor) is allowed to drain off at present. This should not be lost as it contains traces of oil. It would be better if it is let back into the boiler.
- (d) In order to prevent formation of 'boiler-scales' stainless steel is said to be better for the making of these stills instead of copper.

(iv) Yield of oil and economics of production

As already stated, lemon-grass is a perennial crop and the average economic life of a plantation may be reckoned at six years. The oil content of lemon-grass leaves varies from 0.25 to 0.50 per cent, but the total recovery of oil from a plantation depends upon many factors. During the first year the yield of the oil is poor and amounts, on an average, to 1½ dozen bottles of 22 oz. each. During the second and third years, the recovery of oil is more and averages 2½ dozen bottles a annually. Thereafter, the yield is reduced to two dozen bottles a

year until the sixth year. The cost of production of oil worked out on the basis of the figures supplied by the Lemon-grass Research Station, Odakkali, Travancore-Cochin is given below:—

		Rs.
(1)	Cost of cultivation during the first year	97-0-0
(2)	Cost of harvesting and extracting 1½ dozen bottles of oil during the first year	90-0-0
(3)	Cost of harvesting and extracting 2½ dozen bottles of oil during the second year	185-0-0
(4)	Cost of harvesting and extracting 2½ dozen bottles of oil during the third year	185-0-0
(5)	Cost of harvesting and extracting 2 dozen bottles of oil during the fourth year	150-0-0
(6)	fifth year	150-0-0
(7)	sixth year	150=0-0
	Total cost of extracting 12½ dozen bottles of oil	1007-0-0

Approximately Rs. 80 per dozen bottles of 22 oz. each.

While the cost of production amounts to Rs. 80 per dozen bottles, the present price is quoted at hardly Rs. 70. Research should, therefore, be directed in cutting down the costs to the minimum.

(v) Total supply of lemon-grass oil

There is no authentic record of either the actual area under lemon-grass cultivation or of the yield of oil in different producing areas. According to official sources, the total acreage under lemongrass cultivation during 1951-52 in the main producing areas amounted to 39,863 acres which was distributed as follows:

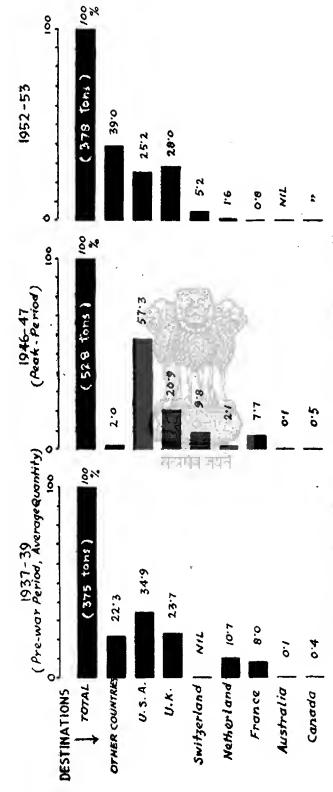

Travancore	e-Cochin		35363	acres		
Malabar		_	4500	"		
	Total	•	39,863	,. or	nearly	40,000 acres

The total yield of oil obtained from this crop during 1951-52 has been estimated at 714 tons. Out of 714 tons of oil produced in India during 1951-52, 634 tons representing 87 per cent were produced in Travancore-Cochin. The quantity of oil produced in the Malabar district was small and amounted to 80 tons representing hardly 13 per cent of the total supply.

From a few tons before the war, the annual production of oil has gradually increased in recent years. The trend of production has been upward, the maximum supply obtained being in 1951-52. Due to lack of demand, distillation has not been rapid in many plantations and the total supply during 1952-53 has not gone up.

(vi) Exports

There are no imports of lemon-grass oil into India. This country exports this oil to the world markets under the trade name of East Indian lemon-grass oil or Cochin lemon-grass oil.

Fi . 33. Percentage export of femon-grass oil from India to different countries of the world

The exports of this oil during 1951-52 amounted to 488 tons or 68·3 per cent of the total annual supply in the country. During world war II, large quantities of the oil were used in the U.S.A. in the synthesis of Vitamin A and in the manufacture of ionones. In recent years, there has been a lack of demand from these sources and this has resulted in appreciable decline in the exports and prices of this oil.

The U.K. is our next important customer. The demand from this source has remained more or less steady. Before the war, the U.K. took 89 tons of Cochin oil representing 23.7 per cent of the total exports. The post-war exports have declined slightly to 84 tons representing only 18.2 per cent of the annual exports from India.

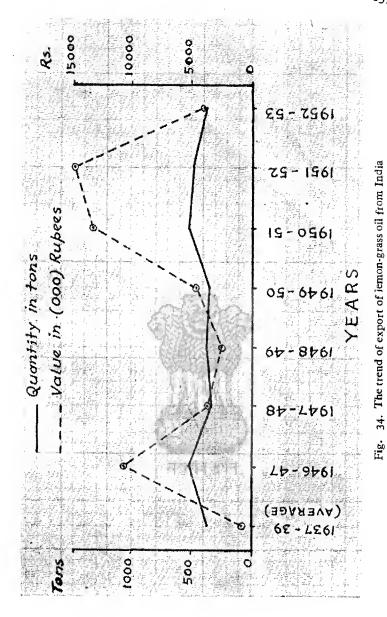

Other foreign markets for this oil are Australia, Netherlands, France and other Continental countries of which France is the most important. The off-take of this country has steadily increased from 30:1 tons before the war to 42 tons during the present time (vide appendix XXXV). Here, the oil is used chiefly in the cosmctic and perfumery industry. Australia is a new customer for the Indian oil and the trade with this country has developed during the war. Netherlands used to import comparatively larger quantities of this oil from India before the war but the post-war figures show considerable decline. Though in small quantities, India exported this oil to Canada also. In order to improve our exchange position, the possibility for increasing trade with these countries should be explored by Indian Government Trade Representatives abroad. Cochin is the most important market for this product in India and almost the entire foreign exports take place through this port. The total value of these exports has also steadily increased. From hardly Rs. 7 lakhs worth of oil exported before the war, the total value increased and amounted to Rs. 149 crores in 1951-52, bulk of which was earned in dollars. During 1952-53 the quantity and value have declined (vide graphs).

(vii) Quality of oil

In the world trade, the oil of Indian origin is known by the name of East Indian lemon-grass oil or Cochin lemon-grass oil while the products obtained from other sources are known as West Indian lemon-grass oil. The quality of these oils is judged mainly by their citral-content and solubility in alcohol. In respect of both these factors, the Indian product has been found to be far superior to the West Indian product.

The citral-content of Cochin oil has been found to vary from 41 to 85 per cent by volume and more than half of the commercial samples from India have been found to have a citral-content above 65 per cent.

Though the commercial samples contain citral up to 85 per cent, the exports to foreign countries are generally of only one quality containing 75-77 per cent citral. There is, therefore, no incentive to ship oil with greater citral-content. Better quality oil is, therefore, toned down to 77 per cent citral-content with oil obtained from white grass, or even mineral oils have been used for adulteration by unscrupulous businessmen. All these reduce the solubility of the oil in alcohol and thus reduce its utility for many of its industrial

सन्त्रपंत्र नवने

uses, particularly in the perfumery industry. Considering the competition from other sources and the present decline in the world markets for this product, we should take early steps to gain the confidence of our foreign customers by firmly establishing the reputation of our product by means of proper quality control.

The Indian Standards Institution has framed the following draft specifications for Indian lemon-grass oil:

General. It shall be a clear liquid and free from sediment, suspended matter, separated water and added adulterants.

Solubility. Unless otherwise agreed between the purchaser and the seller, lemon-grass oil shall be soluble in 2-3 volumes of ethyl alcohol, 70 per cent by volume, occasionally with slight turbidity.

Colour and appearance. Reddish-yellow to brown mobile liquid.

Odour. Lemon-like.

Citral-content. Minimum 75 per cent by volume.

These minimum standards should be adopted for this oil with suitable modifications under the Agricultural Produce (Grading and Marking) Act and the Central Government should prohibit the export from India of all sub-standard qualities under the provisions of the Sea Customs Act.

After extraction, the oil is generally stored in glass bottles of capacities varying from 24 to 28 oz. the standard size being only 22 oz. For export purposes, 40-45 gallon steel drums are used. While the metallic containers serve the purpose well, storage in bottles often involves deterioration in quality on account of exposure to light. This loss should be minimised by keeping the bottles in cool and shady places.

(viii) Unit of sale

The unit usually adopted for the sale of the Indian lemon-grass oil is a box containing one dozen bottles of oil. The capacity of the bottles varies from 24 to 28 oz. in the producing and assembling centres while in the terminal markets, the standard bottles have a uniform capacity of 22 oz. The larger measures in use in the primary markets are often manipulated against the interests of the producers. The unit of sale in all the markets should, therefore, be standardised and should consist of standard bottles of 22 oz. only.

The unit of sale should be a standard box containing one dozen bottles of 22 oz. each and weighing $16\frac{1}{2}$ lb.

(ix) Prices

The post-war prices of Cochin oil have shown a steady increase as may be seen from Table I.

Average annual price of Indian lemon-grass oil per box of dozen bottles

Year	Price (Rs.)
1947-48	65
1948-49	60
1949-50	121
1950-51	216
1951-52	220
1953 (January)	70

After maintaining a steady trend at Rs. 60-65 per box of oil during 1947-48 and 1948-49, the prices increased to Rs. 121 in 1949-50. It registered further rises in the subsequent years and stood at Rs. 220 during 1951-52. The maximum price of Rs. 350 was obtained in March 1951. During the last few months, however, the prices of this oil have shown a downward trend and have fallen to Rs. 65 to 70 at the present time (vide appendix XXXVI).

It is clear that the present price level is unremunerative and does not cover even the cost of production of this oil which has been estimated at Rs. 80 at the Government Farm, Odakkali, Travancore-Cochin. Unless the prices improve and the producers are enabled to get at least the production costs, the industry is bound to suffer and most of the existing lemon-grass farms are likely to be neglected.

This decline in prices is largely attributed to the larger supplies of oil obtained from Guatemala during the season and also to the weak demand for this product from the manufacturing industries in the U.S.A. and other countries. As there is no immediate prospect of improvement in this price situation, it is necessary to reduce the production costs. Simultaneously, steps should be taken to increase the demand for this oil for industrial purposes within the country. Preliminary investigations carried out in Travancore-Cochin have proved that it is possible to manufacture ionones from this oil in India. Steps should, therefore, be taken to set up a pilot plant for the preparation of these synthetic products on a commercial scale within the country and encourage their utilisation in Indian industries.

(x) Assembling and distribution

Cochin is the most important market for lemon-grass oil in India. The main assembling centre is located about 16 miles from the port of Cochin at a place called Kuruppampadi by the producers themselves or by the village merchants. The village merchants in the primary markets or at Kuruppampadi make purchases in small lots on the basis of 24-28 oz. bottles. The merchants at Kuruppampadi generally act as agents of the shippers at Cochin. They examine the quality of the oil with 2-3 parts of 70 per cent ethyl alcohol in which it should be soluble with slight turbidity. At Kuruppampadi when adequate oil is purchased, it is transferred to 40-45 gallon steel drums and transported first to the shippers at Alwaye by road and from there by boat to the Cochin port for shipment.

At Alwaye, the shippers filter the oil and determine the actual citral-content of the samples. Under the shipping contract, the exporters have to guarantee a minimum citral-content of 75 per cent in the sample. In order to ensure this minimum citral-content at the destination and to make allowances for the loss in transit or storage, the shippers generally keep a target of 77 per cent citral in all exports. As many commercial samples contain up to nearly 85 per cent citral-content, the shippers blend it with the oil of the white-stemmed lemon-grass so as to bring down the citral-content of the shipments to 77 per cent. This encourages adulteration with oils of inferior quality and also bring down the reputation of the Indian product in the world markets. With a view to encouraging exports of better quality oils with higher citral-content, we recommend that the fair average quality of the exports should be fixed at 75 per cent citral-content and the exporters should be given a higher premium for increase in citral-content up to 85 per cent.

The lemon-grass oil trade in India is at present in the hands of a small number of shippers operating at Alwaye and Cochin. The small quantity of oil produced in the Malabar district also finds its way to Cochin and is exported through this small coterie of shippers. Most of the village merchants act as agents of these big shippers who advance loans for the purchase of these oils on their behalf in the producing areas.

Thus between the producers and the shippers, the village merchants act as middlemen whose interests are always identical with those of the shippers'. The ignorance of the producers who bring only small quantities of oil for sale and the differences in the capacity of bottles used for buying and selling are often used in manipulating the prices paid to the producers. Standardisation of the units for purchase and sale and other market practices under the Regulation of Market Act will go a long way in remedying these defects in the internal marketing system.

3. RESEARCH, TECHNOLOGY AND DEVELOPMENT

Considering the important lemon-grass oil industry for the State, the Government of Travancore-Cochin have started a Lemon-grass Research Station at Odakkali. Though necessary land has been acquired and the officer-in-charge has been appointed, the Farm has not been brought into working condition for conducting botanical, 128 I.C. of A.R.

chemical and agronomic studies. The authorities of the States concerned have not also made any progress in improving the efficiency of the existing types of country stills.

Under the Essential Oil Development Scheme, the Government of Travancore-Cochin have already carried out preliminary investigations regarding the possibilities of ionone manufacture in India. The utilisation of this oil in the manufacture of other synthetic products, however, requires further research and experimentation.

4. SUMMARY OF CONCLUSIONS AND RECOMMENDATIONS

(i) General outlook

Although India is the largest supplier of lemon-grass oil in the world markets, the total demand for this Indian product has declined since last year. This is attributed partly to larger supplies received from Guatemala and partly to the curtailment of demand from the manufacturers in America and other foreign countries. Unless steps are taken to find alternative uses for this oil in India, the prospects of this Indian industry are not bright.

(ii) Commercial manufacture of ionones

Lemon-grass is a basic raw material for the manufacture of many aromatic substances which are used in the perfume, soap and cosmetic industries. Preliminary investigations carried out by the Government of Travancore-Cochin have shown the possibility of utilising Indian lemon-grass oil in the manufacture of ionones and in the synthesis of vitamin A. A pilot plant should, therefore, be set up in this State and early arrangements made for the commercial manufacture of ionones and other products. The Central Government should subsidise this project and encourage the use of these manufactured products in the Indian industries.

(iii) Adequate supply of red-stemmed grass seeds

The cultivation of lemon-grass is simple and presents no difficulty but in most of the fields the cultivated variety of red stemmed grass is often found mixed with a white-stemmed variety which yields an inferior quality of oil. In order to prevent such admixtures, adequate arrangements should be made for the supply of sufficient quantities of seeds of the red-stemmed grass. The Lemon-grass Research Station at Odakkali, Travancore-Cochin which has facilities for the cultivation of this grass, could be entrusted with arrangements in this connection.

(iv) Need for improved type of country still

The present type of country stills used in India for the distillation of oil are crude in design and construction and involve considerable wastage. It has been found that by adopting steam distillation both the total recovery and the quality of the oil could be increased by about 20 per cent. In order to reduce the costs of extraction and to improve the quality, there is need for evolving an improved type of equipment in the producing areas for the distillation of oil from lemon-grass. The governments of Travancore-Cochin and Madras

and the Central Government should take early steps in this direction and arrange to supply improved type of stills to the producers on a subsidised basis.

(v) Mutual allowances for quality of oil

Although Indian lemon-grass oil contains up to 85 per cent citral, the shippers are asked to guarantee only a minimum of 75 per cent citral-content in their consignments under the present shipping contract terms. This provision encourages adulteration and also unnecessarily brings down the reputation of the Indian product. The producers are also not able to realise the premium for better quality of their products. The trade contract terms should, therefore, be amended so as to guarantee a minimum citral-content of 75 per cent and provide for payment of premium for any higher citral-content above 75 per cent. The Indian Standards Institution has prescribed minimum standards of quality for Indian lemon-grass oil. These standards should be suitably amended under the Agricultural Produce (Grading and Marking) Act so as to provide mutual allowances for quality as stated above on the basis of citral-content.

(vi) Preventing export of sub-standard qualities

Necessary arrangements should also be made to prevent the export of sub-standard qualities for India under the provisions of the Central Sea Customs Act.

(vii) Cooperative marketing

The extraction and marketing of the oil is all done by a small number of producers. Greater economies could be effected in installation charges and manufacturing costs if they could combine themselves into cooperative marketing societies.

Such societies should own laboratories for the regular testing of the oil and its correct determination of citral-content and other quality factors. Necessary facilities should be given by the Governments at the Centre and the States in organising such cooperatives.

(viji) Uniform weights and measures

The weights and measures used in the marketing of lemon-grass oil in the primary and terminal markets are not uniform. A bottle in the primary markets contain 24 to 28 oz. of oil while in the terminal markets, the capacity of the bottle is uniformly 22 oz. As this system often causes confusion and hardship to the producers, arrangements should be made to adopt uniform weights and measures and also to regulate the marketing of this product under the Regulated Markets Act.

(ix) Maintenance of statistics

Reliable statistics of acreage under lemon-grass or of the supply of oil are not available in the different producing States. The Governments of Travancore-Cochin and Madras which are the most important producers of this oil should arrange to collect this information and regularly publish it in their season and crop reports

(x) Market-news service

Very little reliable information regarding supply, stocks, demand and prices of this oil filters down from the exporters to the producers in the village markets. The need for such commercial intelligence exists greatly in Travancore-Cochin and Malabar. The Governments of the respective States should arrange to disseminate such news regularly in the rural markets through bulletins and broadcasts from regional stations of the All India Radio.

(xi) Organisation for development

The central and regional committees for spices proposed in the case of pepper should function also for carrying out the various measures which we have recommended for developing the lemon-grass oil industry in India.

INDIAN COUNCIL OF AGRICULTURAL RESEARCH

ENQUIRY FORM

Please return to the Secretary, Indian Council of Agricultural Research, Jamnagar House Hutments, New Delhi.)

Name of informant
Address
Date
Name of commodity

(Separate form to be used for each commodity)

QUESTION

I.--PRODUCTION.

- (1) What is the area under the crops in your State?
- (2) What is the annual production of the crop?
- (3) What are the conditions suitable for cultivation? E.G., (a) Soil, (b) Climate, (c) Rainfall, etc.
- (4) What is the average area under the crop for cultivator?
 - (i) Is this crop being grown on plantations basis in your State? If so state the percentage area under the different sizes of plantation, i.e., below 1 acre; below 1 to 3 acres; below 3 to 5 acres; below 5 to 10 acres, above 10 acres.
- (5) Does the present tenancy law and practice in your State hinder extension of cultivation of the crop? If so, how and in what manner?
- (6) How are seed and planting material obtained? More particularly with reference to the type, quality and cost?
- (7) What arrangements exist for supply of plants and planting material for cultivators?
- (8) Is there any arrangement to see whether seeds and planting material are free from diseases?
- (9) What are the important pests and diseases of the crop?
- (10) What are the arrangements to see from time to time that plantations are free from pests and diseases?
- (11) What arrangements exist to control pests and diseases?
- (12) Is there any loss by pilferage? If so, what is the approximate expenditure?

- (13) What steps in your opinion are necessary to avoid the pilferage?

 Does pilferage affect the quality of the marked produce? If so, how?
- (14) Are the seeds used indigenous or exotic? If exotic, from which countries are they imported and in what quantities annually?

II.—CULTURAL PRACTICES.

- (15) What are the important cultural practices adopted for proper cultivation. E.G., Preparation of land, seed rate, distances between rows, etc.
- (16) What manure is commonly used?
- (17) Is it available in sufficient quantities?
- (18) If not, what measures do you suggest for obtaining adequate quantities of manure?
- (19) Are chemical fertilisers used to step up production? If so, what is the average rate per acre and what percentage of the total area under the crop which is so manured?

III.—IRRIGATION.

- (20) Does the crop entirely depend on annual rainfall?
- (21) Is the present rainfall sufficient for cultivation?
- (22) Are irrigation facilities besides, rainfall, needed for stepping up production? If so, what are your suggestions of practical possibilities?
- (23) Please indicate possibilities of increasing:—
 - (a) Area, (b) Yield per acre.
- (24) Please give reasons why available additional area, if any, has not been utilised for increased production.
- (25) How can yield per acre be increased and what are the present difficulties?
- (26) Has any research been undertaken to increase the yield per acre?

IV.—MARKETING.

- (27) What is the stage at which crop is harvested, i.e., mature or immature?
- (28) Is there any tendency to harvest immature crop on account of economic or other factors?
- (29) Are any malpractices employed by farmers? E.G., Adulteration before selling.
- (30) What is the nature and extent of such malpractices?
- (31) What is the method employed for processing before marketing and cost of processing for Bengal maund (82 lbs.)?
- (32) Is it in your opinion high and can it be reduced? If so, how?
- (33) Are packing materials available in the country? What is the cost of packing?
- (34) Indicate the quality of packing material imported from abroad and its approximate value per annum.
- (35) How does the farmer sell his produce?
- (36) Please indicate the methods of price fixation at the time the farmer sells his produce.

- (37) Is there a monopoly or is there any syndicate for the produce? If so, explain its nature, advantages and disadvantages.
- (38) Compare farmer's price with prices prevailing in key markets like Bombay and Alleppy for the same quality of goods.
- (39) Are there any malpractices in the villages in regard to weighing, brokerage, commission, charity, etc.? If so, explain them.
- (40) What are the malpractices exercised by traders?
- (41) Please indicate briefly the stages through which the goods pass from the farmer till they reach the final exporter or consumer. Indicate the price at each stage with reference to standard unit 82:2/7 lbs.

V.—GRADING AND STANDARDISATION.

- (42) What are the factors which determine qualities for (i) internal consumption, and (ii) export in respect of demand for different purposes, e.g., as spice, for medicinal purposes, for table and other purposes, etc.
- (43) Please describe in brief the practices followed by the producers, merchants and exporters in the grading of the produce.
- (44) Are there any private or trade standards or conventions regarding quality? If so, describe in brief.
- (45) In what manner such private standards or conventions are effectively enforced?
- (46) Is the crop graded under the Agricultural Produce (Grading and Marketing) Act, 1937?
- (47) What would be advantages and difficulties in grading the crop on the basis of all-India standards of quality?
- (48) State the desirability or otherwise of regulating quality of exports on the basis of standards.
- (49) Can we effectively regulate quality control by entrusting it to the trade? If so, how?
- (50) Would export quality regulation result in improving the export trade and reducing losses?
- (51) Are there any standard contract terms under which business is done in the produce? If so, give details and state how and to what extent such terms are enforced?
- (52) What are your views about the introduction of standards of market or business practices in the primary, terminal and export markets?

VI.—EXPORTS.

- (53) Which are the principal foreign countries which at present import our produce?
- (54) Are there any complaints of foreign buyers regarding quality, absence of grading, adulteration, etc.? If so, please state the nature and extent of those complaints.
- (55) What are your suggestions for meeting these complaints?

VII.—TRANSPORT AND STORAGE.

- (56) What are the modes of communication and transport between villages and assembling markets?
- (57) What is their condition during the marketing and other seasons?

- (58) What is the cost of transport per Bengal Maund of 82:2/7 lbs. per mile by road and by water?
- (59) Do delays and losses occur on account of transport difficulties? If so, please state the nature and extent?
- (60) What are the storing arrangements for the produce in—
 (i) villages, (ii) principal assembling markets, and (iii) port towns?
 - Indicate the methods and cost of financing storing.
- (61) Would it be feasible to organise statutory licensed warehouses for facilitating market finance?

VIII.—FINANCE.

- (62) Is the individual grower in need of finance to undertake cultivation?
- (63) If so, how does he arrange for credit? Could you indicate the cost of credit from private sources and co-operative societies? What are the other advantages and disadvantages between the two credit facilities?

IX.—CO-OPERATIVE MARKETING.

- (64) What is the number of co-operative marketing societies which deal in the produce?
- (65) Please indicate the progress of co-operative marketing in the produce during the 5 years ending 1950-51.
- (66) What are the principal difficulties in extending co-operative marketing and what remedies you would suggest?

X.—MISCELLANEOUS.

- (67) Is there any machinery or organisation for promoting marketing improvements including co-operative marketing and for the collection and dissemination of marketing statistics and information?
- (68) If so, are you satisfied with the working of this machinery? If not, what are your suggestions?
- (69) What are the principal by-products obtained in the production and processing of the crop and what is the volume of production of these by-products?
- (70) Please give suggestions for improving the production, processing, quality standards and marketing of these by-products.

QUESTION

Under Question No. 5.

If you are aware of any particular regions where the cultivation can be extended or newly introduced, please mention them.

Would you suggest that the Forest Departments in the States may be asked to include these (cashew and pepper especially) in their planting programme in the State forests?

Would you advise mixed cropping for some of these, such as the growing of lemon-grass in among cashew plantations, or among trees or other standards on which pepper may be growing.

Under Question No. 6.

Please state the names of varieties of which you may have practical experience, which may possess outstanding characteristics such as high yield, earliness, freedom from diseases, oil outturn, quality of produce and so on. Please state also the centres from where planting material of these varieties can be obtained.

Would you suggest that nurseries should be started in a number of centres by Government for the supply of seed or planting material to growers, as is being done now for Cocoanuts, or/and by subsidised private nurseries to be run under the supervision of Government Officers.

In the case of cardamoms would you prefer the planting of rhyzomes to that of seedlings, and if so what arrangements would you suggest for the supply.

Under Question No. 9.

In each case please estimate the money value of the loss, if possible. Please describe the methods of control recommended by the Agricultural departments (or in local usage) which you may have tried, and state the results. If they have been effective and worthy of general adoption, please state what difficulties, if any, prevent such adoption.

What diseases or pests are the most serious and require scientific investigation?

Under Question No. 11.

Are any manurial experiments being conducted at peresent? If not, on what basis are you fixing your manure doses? Would you recommend the laying out of a number of manurial experiment centres on private estates in addition to those on Government farms.

Under Question No. 27.

Is machinery of any kind being used in the cultivation at any stage, from preparing the field to gathering the crop, and conversion of the same into the form in which it is usually marketed? Have you found them satisfactory enough to be recommended for wider adoption? For which particular processes do you consider that there is scope and need for the use of machinery under present conditions?

Under Question No. 28.

What provision exists at present for scientific research and experiment, on the various aspects of production and processing; if you consider them inadequate, please state in what respects and suggest improvements.

APPENDICES 151

Under Question No. 31.

In the case of cardamoms, what method would you suggest for enabling small producers to dry and cure the crop in efficient driers? Would you advise (1) co-operative driers at convenient centres, (2) sale of green (undried) cardamoms to the larger producers owning efficient modern driers, in the same way as tea-leaves are sold to factories.

Do you bleach your cardamoms before sale? If so please describe the method. Would you make the practice general as a means of getting enhanced prices.

As the export of cardamoms to the U.S.A. (1948-49) amounts to a mere 310 cwts. out of a total export of 17,506 cwts, can you suggest any measures for increasing this quantity, so as to materially enhance its dollar-earning capacity.

In the case of cashewnuts, is the 'Vitapack' method of export packing known in all the cashew-growing tracts, and especially in the cast coast production tracts? Has any attempt been made to introduce it there? Do you consider it would be worth while to do so?

Are you adopting only the open pan roasting method of preparing the nuts or using any improved method? In the latter case please describe it and state if you would advise its general adoption.

Has the new patented method now being advertised for shelling the nuts by machinery been tried by you or any one you know of, and has it been found satisfactory?

Has the cashew "apple" been put to any large-scale commercial use? What is your opinion about the scope and prospects of any such venture?

Under Question No. 60.

Does the produce deteriorate in any manner in storage? Are there any storage pests, and what remedies are applied? What is the maximum period during which storage can be made, without any deterioration?

सरमध्य मध्य

Under Question No. 66.

Do these societies pay advances on estimated produce or pay only after produce is actually delivered? In the former case, how do they guard themselves against loss due to (1) member failing to market his produce through the society, (2) a steep fall in prices in the interval. Would you suggest that in the case of all produce-selling societies such dues should be collected like arrears of land revenue by the Government?

In view of possible low prices due to over-production as the result of the present stimulus of soaring prices, and to a return to normal times, would you suggest the constitution of a Marketing Board for some of these products, somewhat on the lines of the Coffee Marketing Board, which will prevent a steep fall of prices, and at the same time will protect their interests of consumers. Please give your views for or against.

Chief characteristics of local varieties of pepper

Local name of variety	Tracts where commonly	Character+
	cultivated	General
Kottandan	South and Central Travan- core.	Good climber, yearly bearing and a heavy yielder. One of of the best varieties.
Kanarkadan	Central and North Travan- core.	Good climber, yearly bearing and a heavy yielder. One of the best. Two distinct sub-divisions, Valia and Cheria.
Perumkodi	Central and North Tra- vancore.	Medium climber, yearly bearing and a good yielder.
Karivilanchi	South and Central Travan-core.	Medium climber, yearly bearing and a good yielder, a good variety favoured by cultiva- tors and traders. A hardy plant allied to Kalluvalli
Karivalli	Rani	Good climber, bears in alternate years.
Mundi	North Travancore	Medium climber, yearly bear- ing and a good yielder, a hardly and an early varie- ty.
Munda	Central North and Travan-	Medium climber and poor yiel- der.
Arikottanadan	South and Central Travan-	Medium climber and a good yielder.
Thulakodi	Central Travancore	Medium climber and a good yielder, yearly bearing and an early variety.
Kuthirawali	South Travancore	Medium climber, yearly bearing and a good yielder.
Kumbakodi	Central Travancore	Good climber, yearly bear- ing a good yielder and a late variety.
Chumala	Rani	Good climber, yearly bearing and an early variety.
Karinghakara	Central Travancore	Bold climber, a good yielder but bears only in alternate years.
Balamcotta	Kottayam, N. Malabar	Good climber, yearly bearing and a good yielder.
Kalluvalli	North Malabar	Medium climber, yearly bear- ing and good yielder. A hardy plant.

Rules for standard cost, freight (and insurance) contract

- I. Disputes.—Any question, controversy or claim whatever between buyer and seller, arising out of this contract, not adjusted by mutual agreement, shall be settled by arbitration in New York under the rules herein provided.
- 2. Quantity.—It is understood that the word "about" applied to quantity contracted for, means the nearest amount which seller should fairly and reasonably deliver, but no excess or deficiency to be greater than 2 1/2 per cent of the gross weight if sold gross for net or the net weight, if sold with tare allowance. The aforesaid leeway of 2 1/2 per cent. shall be deemed void whenever the contract is liquidated by payment of the difference between purchase and sale in lieu of delivery. Unless otherwise specified the ton shall be considered 2,240 pounds.
- 3. Shipment.—Prompt-shall mean shipment within fourteen days. The date of the Bill of Lading covering the merchandise, shall be prima facie evidence of the date of shipment.

- 4. Declarations.—The name of the vessel shall be declared to the buyer by the seller before arrival of the vessel, and in no case later than two business days after the name of the vessal becomes known to the seller except when seller can show that he was prevented from making such declaration before the vessels arrival by circumstances over which he had no control. No declaration may be withdrawn or changed by seller unless he can show error in the original declaration received, by him. If the merchandise is shipped on more than one vessel, each declaration shall be treated as a separate contract. The word "afloat" shall be deemed to mean that the steamer carrying the merchandise in question shall have left the port of shipment at the date of sale.
- 5. Landed Weights.—Landed weights shall be the actual gross weights; the goods to be weighed at sellers' expense by public weighers, as soon as practicable after landing, in such lots as may be requested by buyer in writing within three days after the arrival of vessel. Extra weighing charges, if caused by buyer's request, to be for buyer's account. Slack and missing packages to be averaged on the basis of the sound portion.
 - 6. Tares.—For Ceylon Cinnamon, actual shipping tares shall govern.

For all other spices, seeds and herbs, in bags or bales unless otherwise provided for, tares shall be actual average, to be ascertained by taring a certain percentage of the sound portion of each chop or invoice, as follows: 100 packages or more, 5 per cent; less than 100 packages 10 per cent but not more than five packages, such percentages to be at least the average gross weight of each chop or invoice.

In case of packing in double bags, tare of the outside bag is to be allowed to buyer and such tare shall likewise be actual average. When terms are gross for net weights, and the goods are packed in double bags, actual average tare for the outside bag shall be allowed to the buyer.

Weigher's returns of tares shall state the gross weight of every package tared.

On all spices and seeds in cases or barrels, marked tares shall govern unless proved to be wrong by a public weigher's certificate.

- 7. Duties.—All Import Duties of the U.S.A. and any U.S.A. Federal State and/or Municipal taxes shall be for account of buyer. All Export Duties, Levies and/or other taxes, if any, levied under Government order in the country of origin shall be for account of seller.
- 8. Import Regulations.—All spices, seeds, tapioca or herbs purchased under this contract shall comply with the rules and standards under which the Food and Drug Administration of the Federal Security Agency or Successor Agency or Agencies enforces the Food, Drug and Cosmetic Act of June 25, 1938, and amendments thereto, at date of signing this contract. If any such merchandise must be reconditioned to comply with these standards, the expense and loss in weight incident thereto shall be for the account of the seller; any reasonable loss in weight on re-conditioning to be considered part of the tender. I oss in weight due to reconditioning to be determined by the difference between the landed weight and weight of the released merchandise after reconditioning.

When goods are sold to be released by the Food and Drug Administration or no sale, expenses of storage, labour, cartage and insurance pending decision, shall be borne by seller if excluded and by buyer if released.

arbitrator.

9. Standards.—All spices, seeds, or herbs purchased under this contract shall comply with the rules under which the Food and Drug Administration or 'the Federal Security Agency or successor agency or agencies enforces the For Drug, and Cosmetic Act of June 25, 1938 and amendments thereto in forced at the date of this contract.

In the case of Black Pepper there shall be attached to the final invoice a certificate of a chemist approved by the American Spice Trade Association showing the quality of each lot with respect to the percentages of light berries and of dust, dirt, chaff, picking and/or other extraneous matter.

Garbled Malabar Pepper shall be subject to an allowance if it contain^S over 1 per cent. by weight of dust, dirt, chaff, pickings or other extraneou^S matter, to be determined by hand picking and by sifting through a 9 1/2 roundhole sieve. The permissible percentage of light berries in Garbled Malabar Pepper shall not exceed 2 per cent.

All other Pepper shall be subject to an allowance if it contains over 2 per cent. by weight of dust, dirt, chaff, pickings, or other extraneous matter, to be determined in the same manner as outlined in the preceding paragraph, and the permissible percentage of light berries shall not exceed 3 per cent in this pepper.

Cloves must be free from mustiness and contain not more than 5 per cent. of stems, mother of cloves, and foreign, superfluous or inferior matter 7 per cent. of Khoker cloves and 16 per cent. of moisture by the Toluor mathod.

14. Arbitration.—The following regulations shall govern all arbitration held under this contract:

B. Arbitrators.—Each disputant shall appoint a disinterested member of the Association as arbitrator. If either disputant shall neglect to appoint an arbitrator within three business days after notice in writing is received by him from the other disputant of the appointment of his arbitrator, the Presiden shall appoint the other arbitrator upon a written request from wither party to the dispute. Disputants may appoint one person to act as sole

* * * * * *

E. Award.—The award of such arbitrators and umpire or sole arbitrator shall be final and binding on both parties, unless within three business days after receipt of the award, an appeal with a fee of Sh. 150 be lodged with the Secretary of the Association by either disputant, Settlements under an arbitration award or award of the Arbitration Committee shall be made within ten days from the date of such award, and if not so settled, judgment may be entered thereon in accordance with the practice of any Court having Jurisdiction.
